INDEX

- AARKROG, A.:** Specific Fall-out Activity In Precipitation as a Function of Sampling Height, 482
- Abe, Tomiya, and others:** Histochemical Demonstration of Aromatic Monoamine in the Locus Coeruleus of the Mammalian Brain, 326
- Abelson, Prof. Denis:** Ultra-Violet Photography of Fluorescent Spots on Chromatograms of Biological Extracts, 850
- Abercrombie, M. L. J.:** At the fifth Annual Conference of the British Society for the Philosophy of Science (Learning to Perceive), 458
- Aberration of the Connective Tissue:** Muscular Dystrophy in the Siamese Fighting Fish as an (Prof. A. Stolk), 751
- Aberration of Plane Waves** (Dr. E. F. Fahy), 396
- Abnormalities (Serum Protein), in 'Runted' Albino Rats** (John S. Thompson and Clifford W. Gurney), 421
- Abnormality (A Possible Specific Chromosome), in Human Chronic Myeloid Leukaemia** (A. G. Baikie, W. M. Courte-Brown, Karin E. Buckton, D. G. Harnden, Patricia A. Jacobs and Isabel M. Tough), 1165
- Abolition by 2:4-Dinitrophenol of the Protective Effect of Succinate and Adenine Nucleotides on the Onset of the Thyroxine-induced Swelling of Liver Mitochondria** (Dr. P. Emmelot), 1197
- Aboriginal and Indigenous Populations:** Blood Groups of Selected (Prof. John Buettner-Janusch, Henry Gershowitz, Leopold J. Pospisil and Peter Wilson), 153
- Absolute Dating of the Middle Ordovician** (Prof. J. A. S. Adams, J. K. Osmond, Dr. G. Edwards and W. Hanle), 636
- Absorption of Soil Phosphorus by Wheat Plants:** Effect of Water-stress on the (R. G. Fawcett and Dr. J. P. Quirk), 687
- Absorption (Ion), and Protein Turnover in Plant Cells:** New Evidence for a Relationship between (Dr. J. F. Sutcliffe), 294
- Absorption Spectra of Copper (II) and Nickel (II) Complexes** (Dr. J. Császár and J. Balog), 402
- Absorption Spectra (Ultra-violet), of the Molecules H₂O, HDO and D₂O** (Prof. W. C. Price, P. V. Harris, Dr. G. H. Beaven and Dr. E. A. Johnson), 45
- Absorption Spectroscopy (Atomic):** Determination of Silver in Lead Concentrates by (B. S. Rawling, M. C. Greaves and M. D. Amos), 137
- Absorption and Excretion of Copper in Mice** (Prof. David Gitlin, Walter L. Hughes and Charles A. Janeway), 150
- Academic Research Freedom in,** 173
- Acanthamoeba at Encystation:** Structural Changes in Mitochondria of (Keith Vickerman), 248
- Accascina, Prof. Filippo (Fusa, Prof. Raymond M., and):** Electrolytic Conductance, review by Prof. J. R. Partington, 1061
- Accelerated Recovery from Reserpine Depression by Monoamine Oxidase Inhibitors** (Larry Stein and Oakley S. Ray), 1199
- Accelerators:** High Voltage (High Voltage Engineering Co. Conference on), 785
- Accidents in Factories:** Checking, 453
- Acellular Teleost Bone:** X-Ray Diffraction Study of (Prof. Melvin L. Moss and Dr. Aaron S. Posner), 1037
- Acetate:** Photo-Assimilation of, by Green Organisms (Prof. E. G. Pringsheim and Dr. W. Wiesner), 919
- Acetate labelled with Carbon-14:** Active Transport of Sodium by Isolated Frog Skin in relation to Metabolism of (J. T. Van Bruggen and K. Zerah), 499
- Acetate-2-¹⁴C:** Metabolism of β -Sitosterol and other Lipids in the Presence of, by Blowfly Larvae (E. Kodicek and Dr. Z. H. Levinson), 1023
- Acetate Tolerance in the Young Lamb** (I. G. Jarrett and O. H. Filsell), 418
- Acetate (Cellulose):** Analysis of Human Leucocyte Deoxyribonucleohistone by Immuno-electrophoresis on (Dr. William A. Atchley), 579
- Achromobacter:** *Pseudomonas* and (Society for Applied Bacteriology Symposium on), 25
- Acid-Base Catalysis:** The Concerted Mechanism in (Dr. F. J. C. Rossotti), 936
- Acid Mucopolysaccharides:** Production of, by Fibroblasts in Cell Cultures (Dr. C. C. Morris and Dr. G. C. Godman), 407
- Acid Phosphatase Activity in Cells of Prostatic Tumours:** Determination of (P. L. Esposti, B. Estborn and J. Zajicek), 663
- Acid-soluble Nucleotides:** Specific Activities of, in Hind-Leg Muscles of Mice with Dystrophia Muscularis (Dr. Michael C. Zymaris, Dr. Abraham Saifer and Dr. Bruno W. Volk), 323
- Acid-soluble Ribonucleotides of Rat Mammary Gland:** Effects of Short-term Weaning on the (Dr. D. Y. Wang), 1109
- Acidic Dissociation Constants of Alcoholic Hydroxyls of Hydroxycarboxylic Acids—Tartaric Acid** (B. Császár and P. Szarvas), 846
- Acids (Organic), in Citrus Leaves:** Changes in Amounts of, during Periods of Cold Storage (Dr. H. T. Freebairn), 243
- Acids (Plant Growth Regulator):** Evidence of a Specific Action on the Central Nervous System by the Esters of some (Dr. J. Thuillier, Germaine Thuillier and P. Rumpf), 152
- Acrocomia Fruit:** Structure of (Dr. J. G. Vaughan), 81
- Acta Imeko 1958—Proceedings of the International Measurements Conference, Budapest, 1958,** review by Dr. H. Barrell, 883
- Actinomycetes:** Transduction in (S. I. Alikhanian, T. S. Ilyin and N. D. Lomovskaya), 245
- Action of the Alkaloid in Mussel Poisoning:** Histochemical Demonstration of the Mode of (W. J. Pepler and E. Loubser), 860
- Action of 6-Aminopenicillanic Acid on Gram-negative Bacteria** (Dr. W. B. Hugo and A. D. Russell), 875
- Action of Creatine Phosphokinase:** A Theory of the Mechanism of (Dr. B. R. Rabin and D. C. Watts), 1163
- Action of Drugs:** Mode of (Section of Pharmacology of the International Union of Physiological Sciences International Pharmacological Meeting on), 784
- Action of Nitrous Acid on Aliphatic Amines** (Dr. A. T. Austin), 1086
- Action of Spermine on Soluble Ribonucleic Acid and some Polynucleotides—Spermine Fractionation of Soluble Ribonucleic Acid of Rabbit Liver** (Dr. G. L. Cantoni), 300
- Solubility of Complexes of Polynucleotides with Spermine** (S. Lee Huang and Dr. G. Felsenfeld), 301
- Action of some Synthetic Peptides of a Protease from Rabbit Spleen** (T. Webb and Cl. Lapresle), 66
- Action of Thymidylate Synthetase:** Mechanism of the (Barbara M. McDougall and Dr. R. L. Blakley), 944
- Action (Carcinogenic):** Griseofulvin and Colchicine—Lack of (Dr. G. E. Paget and Shirley J. Alcock), 867
- Action (Carcinogenic), of Diazomethane and of Nitroso-N-methyl Urethane** (Dr. R. Schoental), 420
- Action (Cardiac), and Pacemaker Potentials based on the Hodgkin-Huxley Equations** (D. Noble), 495
- Action (Different), of 2:4-Dinitrophenol on the Oxidation of Exogenous and Endogenous Substrates by Baker's Yeast** (Prof. A. O. M. Stoppani, Dr. E. H. Ramos and I. Widuchowski), 1188
- Action (Specific), on the Central Nervous System by the Esters of some Plant Growth Regulator Acids:** Evidence of a (Dr. J. Thuillier, Germaine Thuillier and P. Rumpf), 152
- Action (Tryptic and Phosphatase), on certain Synthetic Phosphorylated Peptides** (Dr. D. Theodoropoulos, Prof. J. Gazopoulos and I. Souclieris), 489
- Actions of the Decarboxylase Inhibitor, α -Methyl-3,4-dihydroxyphenylalanine, in the Dog** (Dr. Leon I. Goldner, Frances M. DaCosta and Masayori Ozaki), 502
- Actions (Oxidative and Hydroxylative), of Quartz:** Some—their Possible Relationship to the Development of Silicosis (L. W. Marasas and Dr. J. S. Harrington), 1173
- Activated Hydrogen Peroxide:** Formation of, by Irradiation of Water with α -Rays (Dr. P. Alexander and Dr. D. Rosen), 574
- Activation (Amino-Acid), in Crude Tissue Extracts:** A Method for studying (G. Coleman and Dr. W. H. Elliott), 64
- Activation (Neutron), followed by γ -Ray Spectrometry:** Rapid Analysis of Erbium by (Minoru Okada), 52
- Simultaneous Determination of Scandium and Dysprosium by** (Minoru Okada), 575
- Activation and Reduction of α -Aminoadipic Acid by Yeast Enzyme:** Mechanism of (S. Sagisaka and Prof. K. Shimura), 1189
- Active Sodium Transport:** Inhibition of, by Cholera Toxin (Geraldine J. Fuhrman and Prof. Frederick A. Fuhrman), 71
- Active Transport of Sodium by Isolated Frog Skin in relation to Metabolism of Acetate labelled with Carbon-14** (J. T. Van Bruggen and K. Zerah), 499
- Active-Centre Topography:** Constraints in the Determination of (Marshall W. Nirenberg and William B. Jakoby), 747
- Activities (Specific), of Acid-soluble Nucleotides in Hind-Leg Muscles of Mice with Dystrophia Muscularis** (Dr. Michael C. Zymaris, Dr. Abraham Saifer and Dr. Bruno W. Volk), 323
- Activity of Glutamic-Oxalacetic Transaminase:** Effect of Electrolytes on the (Dr. Aleksandra Smockiewiczowa and Helena Kujawa), 487
- Activity (Acid Phosphatase), in Cells of Prostatic Tumours:** Determination of (P. L. Esposti, B. Estborn and J. Zajicek), 663
- Activity (Aldolase and Phosphatase), in the Cactus Plant:** Diurnal Variation in (G. G. Sanwal and Prof. P. S. Krishnan), 664
- Activity (Antibacterial), of 1-Methyl-3-nitro-1-nitrosoguanidine:** A Factor in Agar which reverses the (Dr. Joseph Greenberg), 660
- Activity (Argininosuccinase), in Brain Tissue** (S. Tomlinson and R. G. Westall), 235
- Activity (Biological):** Correlation of, and the Electron Spin Resonance Signal Strength from Guinea Pig Adrenals (Frank K. Truby and Dr. Joseph W. Goldzeher), 1088
- Activity (Catalase), of Mouse Liver and its relation to the Condition of the Animal** (Dr. K. G. van Senden and J. de Jong), 1116
- Activity (5-Deoxycytidylic Acid-deaminating), in Human Gastric Mucosa and other Adult Mammalian Tissues** (Dino Guerritore, Vincenzo Rocchi and Andrea Setzu), 146
- Activity (Fibrinogenolytic), in Plasma:** The 'Serial Thrombin Time' Method for measuring (Dr. G. L. C. Ingram and Myrtle O. Matchett), 674
- Activity (Haemagglutinating), of some Para-influenza Viruses:** Effect of Ultrasonic Vibration on the (Svante Hermodsson), 1214
- Activity (Insulin):** Regeneration of, from the Separated and Inactive A and B Chains (Dr. G. H. Dixon and Dr. A. C. Wardlaw), 721
- Activity (Juvenile Hormone), in Micro-organisms and Plants** (Prof. Howard A. Schneiderman, Dr. Lawrence I. Gilbert and Dr. Marvin J. Weinstein), 1041
- Activity (Optical):** Examination of γ -Irradiated Benzene for (Leonard Spalter and Jean H. Futrell), 225
- Activity (Oxidative), of a Particulate Fraction from *Rumex* Virus Tumour Tissue** (Prof. A. C. Gentile), 851
- Activity (Plant Growth Regulating), of Auxin-Type Chemicals:** Morphological Reactions of Germinating Seeds as Criteria for the (J. Sidi, Gy. Josepovits and Gy. Matolcsy), 244
- Activity (Specific Fall-out), in Precipitation as a Function of Sampling Height** (A. Aarkrog), 482
- Activity (Spontaneous), in the Central Nervous System of the Crayfish:** Effects of γ -Aminobutyric Acid and Picrotoxin on (Prof. Joseph K. Hichar), 1117
- Activity (Spontaneous), in the Optic Nerve:** Disuse of a Central Synapse and (Dr. W. Burke and Dr. W. R. Hayhow), 668
- Activity (Thymidylate Kinase):** Stabilization of, by Thymidylate and by Thymidine (Dr. Tadeusz Bojarski and Howard H. Hiatt), 1112

- Activity (Transforming), of Deoxyribonucleic Acid labelled with 5-Bromouracil (Prof. Wacław Szybalski, Z. Opara-Kubinska, Dr. Z. Lorkiewicz, Dr. Erela Ephraïm-Eltzur and Prof. Stephen Zamenhof), 743
- Activity (Urinary β -Glucuronidase): Schistosomiasis and (P. J. Fripp), 507
- Activity and Recovery: Incorporation of Amino-Acids labelled with Carbon-14 in Nerve Proteins during (Mario Luxoro), 1119
- Acton, Prof. Forman S.: Analysis of Straight-Line Data, review by Dr. D. J. Finney, 176
- Actual Research and Medico-sanitary Problems: National Health Institutes and (World Health Organization International Symposium on), 711
- Ada, G. L. (Anderson, Dr. S. G., and): A Lipid Component of Murray Valley Encephalitis Virus, 876
- Adam, Dr. Hans: Different Types of Body Movement in the Hagfish, *Myxine glutinosa* L., 595
- Adams, Dr. C. E.: Embryonic Mortality induced Experimentally in the Rabbit, 332
- Adams, Prof. J. A. S., and others: Absolute Dating of the Middle Ordovician, 636
- Adams, Dr. J. B.: Awarded the Duddell Medal of the Institute of Physics and the Physical Society, 710
- Adams, M. J., and Jacob, L.: Electrical Conductivity of Strontium Oxide, 130
- Adams, Roger, and others (edited by): Organic Reactions, Vol. 10, review by Prof. John Read, 836
- Adams-Ray, J., and others: Storage and Release of Catecholamines, and the Occurrence of a Specific Submicroscopic Granulation in Hearts of Cyclostomes, 324
- Adaptation (Visual), in the Rat: Chemistry of (John E. Dowling), 114
- Adaptive Behaviour: The Mechanism of, review by Dr. W. Sluckin, 5
- Adaptive Change in an Inbred Mouse Strain maintained in a Cold Environment (Dr. S. A. Barnett), 500
- Addition Polymers: Linear and Stereo-regular (Norman G. Gaylord and Herman F. Mark), review by Prof. C. E. H. Bawn, 179
- Additives (Inorganic Sulphide): Frictional Properties of Molybdenum Disulphide Films containing (A. J. Haltner and C. S. Oliver), 308
- Adenine Nucleotides: Abolition by 2,4-Dinitrophenol of the Protective Effect of Succinate and, on the Onset of the Thyroxine-induced Swelling of Liver Mitochondria (Dr. P. Emmelot), 1197
- Adhesion of Electrodeposited Metals: Fatty Acids and (Dr. P. A. Brook), 1183
- Adhesion of Oxide (Growth and), in Furnace Deposits (J. Steel), 1187
- Adiabatic Flame: Nitric Oxide Reduction in Methyl Nitrite Pyrolysis and the Transition from Isothermal Decomposition to (Dr. Peter Gray and Dr. A. Williams), 56
- Adiantum capillus-veneris*: Colchic-Autotetraploidy in (S. C. Verma and Dr. D. S. Loyal), 1210
- Adler, Dr. Howard I., and Haskins, Sara D.: Heterogeneity of Cultures of *Escherichia coli* B/r, 249
- Administration (University): Automatic Data-processing in, 710
- Admiralty Signal Establishment: Promotion of R. Benjamin to Deputy Chief Scientific Officer, 280
- Admission of Students: Procedure for (Association of Universities of the British Commonwealth), 716
- Admissions to British Universities, 716
- Adrenal Cortex: Importance of Insulin and of the, in determining the Toxicity in Baboons (*Popio ursinus*) of Human Anterior Pituitary (Prof. Joseph Gillman, Christine Gilbert and Edward Epstein), 861
- Adrenaline and Blood Lipids (Dr. A. N. Granitzas, E. D. Kuvelas and A. Konstantopoulos), 1115
- Adrenals (Guinea Pig): Correlation of Biological Activity and the Electron Spin Resonance Signal Strength from (Frank K. Truby and Dr. Joseph W. Goldzieher), 1088
- Adrian, Lord: The Sense of Hearing, 270
- Adsorption (Heat of), of Hydrogen on Tungsten at Elevated Temperatures (F. M. Page), 1021
- Adsorption (Negative and Positive), of Chloride by Kaolinite (Dr. J. P. Quirk), 253
- Adult Hamsters: Induction of Tumours by Polyoma in (Dr. V. Defendi), 508
- Adult Mammalian Tissues: 5-Deoxyxycytidylic Acid-deaminating Activity in Human Gastric Mucosa and other (Dino Guerritore, Vincenzo Rocchi and Andrea Setzu), 146
- Adults: Television and, 996
- Advanced Technology: Colleges of, 1137
- Advanced Technology, Northampton College of (London): Courses on Collecting and Communicating Scientific Information, 1153
- Advancement (Scientific and Technological): Prospects of, review by Sir Harry Melville, 807
- Advances in Aeronomy: Recent (International Association of Geomagnetism and Aeronomy Symposium on), 712
- Advances in Applied Mechanics (edited by H. L. Dryden, Th. von Kármán and G. Kuerti), Vol. 6, review by Dr. Ian Proudman, 352
- Advances in Applied Microbiology (edited by Wayne W. Umbreit), Vol. 2, review by Dr. J. W. G. Porter, 812
- Advances in Enzymology and related Subjects of Biochemistry (edited by F. F. Nord), Vol. 21, review by Dr. Edwin C. Webb, 821
- Advances in Geophysics, Vol. 6, Atmospheric Diffusion and Air Pollution—Proceedings of a Symposium held at Oxford, 1958 (edited by Dr. F. N. Frenkel and Prof. P. A. Sheppard), review by Dr. A. C. Best, 837
- Advances in Pest Control Research (edited by R. L. Metcalf), Vol. 3, review by K. A. Lord, 834
- Advances in Space Science (edited by Frederick I. Ordway), Vols. 1 and 2, review by Prof. D. R. Bates, 885
- Adventure, Beauty and Science in Africa, review by Dr. A. S. Thomas, 830
- Advisory Committee (Television): Report of the, 1960 (General Post Office), 101
- Advisory Committees: Government Scientific and Technical, 85
- Advisory Committees in British Government (Political and Economic Planning), 85
- Advisory Council on Scientific Policy: Thirteenth Annual Report (1959-60), 435
- Advisory Council (Northern), for Further Education: Thirteenth Annual Report (1959-60), 277
- Advisory and Technical Service: A Commonwealth, 523
- Aerated Aqueous Solution: Effect of X-Rays on Cytosine in (B. Ekart and Prof. R. Monier), 309
- Aerobiology and Medicine (H. A. Hyde), 182
- Aeronautical Society, Royal: Christmas Lecture by R. J. Lees (Gyroscope and Pendulum—the Modern Travel Agents), 1075
- Aeronautical Society (Royal), (Institution of Electrical Engineers and the): Formation of a Joint Committee to consider the Applications of Electricity in Aircraft, 453
- Aeronautics, College of (Cranfield): Appointment of A. Rothwell as lecturer in aircraft design, 24
- Appointment of Dr. A. C. Smith as lecturer in mathematics, 24
- Comparative Efficiency of Indexing Systems (C. W. Cleverdon), 276
- Aeronomy: Recent Advances in (International Association of Geomagnetism and Aeronomy Symposium on), 712
- Aeronomy, International Association of Geomagnetism and (International Union of Geodesy and Geophysics): Gyromagnetic Ratio of the Proton, 192
- Symposium on Recent Advances in Aeronomy, 712
- Aerosols: Physical Chemistry of (Faraday Society Discussion on), 630
- Ætiological Agent of Bovine Malignant Catarrhal Fever: Blue Wildebeest and the (W. Plowright, R. D. Ferris and G. R. Scott), 1167
- Afforestation of Industrial Waste (British Association for the Advancement of Science, Section K* (Forestry), Symposium on), 11
- Africa: Adventure, Beauty and Science in, review by Dr. A. S. Thomas, 830
- Livestock in, review by Sir John Hammond, 813
- Africa (East) High Commission: Appointment of Sir Richard Ramage as Commissioner to examine the arrangements for localization in the East African Posts and Telecommunications Administration, 539
- Africa (Eastern and Southern): The Indigenous Livestock of (I. L. Mason and J. P. Maule), review by Sir John Hammond, 813
- Africa (North): World-wide Distribution of Iodine-131 in Animal Thyroids following Announcements of Isolated Nuclear Weapons Tests in (Prof. L. Van Middlesworth), 748
- Africa (Tropical East) Flora of, review by J. P. M. Brenan, 1142
- African Ornithology, Percy Fitzpatrick Institute of: Appointment of Dr. J. M. Winterbottom as director, 193
- African Pyrethrum Technical Information Centre: Appointment of Dr. J. R. Furlong to take charge of the London office, 988
- African (East) Posts and Telecommunications Administration: Appointment of Sir Richard Ramage as Commissioner to examine the arrangements for localization in the, 539
- Afzelius, B.: Biological Structure and Function (Electron Microscopy Studies on Ciliary and Flagellar Movements), 1160
- Agar: A Factor in, which reverses the Antibacterial Activity of 1-Methyl-3-nitro-1-nitrosoguanidine (Dr. Joseph Greenberg), 660
- Agar Gel: A Method for the Direct Detection of Proteolytic Enzymes after Electrophoresis in (Dr. José Uriel), 853
- Agar Gel Electrophoresis: Studies on (Dr. R. J. Wieme), review by Dr. R. Consden, 8
- Agar-Gel Precipitation Pattern: Misinterpretation of an (Dr. J. G. Felnerberg), 684; (J. Pepps, R. W. Riddell and Y. M. Clayton), 685
- Agarics and Boletii (British): New Check List of (R. W. G. Dennis, P. D. Orton and F. B. Hora), 284
- Age (Known) Samples: Carbon-14 Measurements of (Elizabeth K. Ralph and Robert Stuckenrath, jun.), 185
- Age (The Stone), in Jersey—Saint Brélade's Cave (Father Christian Burdo), 105
- Ageing of Haemoglobin (Jean Rosa, Jean-Claude Drèyfuss and Prof. Georges Schapira), 753
- Ageing Individual: The, review by Prof. L. S. Hearnshaw, 614
- Agent (Ætiological), of Bovine Malignant Catarrhal Fever: Blue Wildebeest and the (W. Plowright, R. D. Ferris and G. R. Scott), 1167
- Agents (Chelating): Effect of, on Plasmodium Formation by the True Slime Mould, *Didymium nigripes* (Prof. Norman S. Kerr), 1206
- Agents (Twitch-potentiating), at the Neuromuscular Junction: Interaction between Repetitive Nerve Stimulation and (Prof. Albert S. Kuperman and Gerhard Werner), 1032
- Ages (Exposure), for Iron Meteorites (Dr. H. Wänke), 1101; (Dr. Oliver A. Schaeffer), 1102
- Ageing and the Individual: Handbook of—Psychological and Biological Aspects (edited by Dr. James E. Birren), review by Prof. L. S. Hearnshaw, 614
- Agpol Foreign Trade, Advertising and Publishing Agency, Warsaw: New Polish Publications, Nos. 1-5, 784
- Agricultural Botany, National Institute of: Crop Conference, 627
- Agricultural Meteorology (Royal Meteorological Society Symposium on), 541
- Agricultural Research, Indian Council of: *Indian Potato Journal*, 105
- Agricultural Research Council: Report for 1958-59, 25
- Promotion of Dr. R. A. Beatty (Unit of Animal Genetics, Edinburgh) to Senior Principal Scientific Officer, 281
- Promotion of Dr. R. M. C. Dawson (Institute of Animal Physiology, Babraham) to Senior Principal Scientific Officer, 281
- Promotion of Dr. R. F. Glascock (National Institute of Research in Dairying, Reading) to Senior Principal Scientific Officer, 281
- Promotion of Dr. C. G. Johnson (Rothamsted Experimental Station, Harpenden) to Senior Principal Scientific Officer, 281
- Appointment of Dr. Richard Keynes (Institute of Animal Physiology, Babraham) as head of the Physiology Department, 364
- Appointment of Dr. Theodore Gillman (Institute of Animal Physiology, Babraham) as head of the Experimental Pathology Department, 364
- Appointment of Dr. G. D. Greville (Institute of Animal Physiology, Babraham) as head of the Biochemistry Department, 365
- Appointment of Dr. Marthe Vogt (Institute of Animal Physiology, Babraham) as head of the new Pharmacology Unit, 365
- Grant from the Wellcome Trust to the Virus Research Unit, Cambridge, for special research apparatus, 454
- Agriculture and Fisheries for Scotland, Department of: Marine Research 1960, No. 2, Seals and Scottish Fisheries (Dr. Bennet B. Rae), 774
- Agriculture, Fisheries and Food, Ministry of: Promotion of Dr. N. Uri (Research Establishment and Experimental Factory, Aberdeen) to Senior Principal Scientific Officer, 281
- Agriculture and Urban Growth (Dr. G. P. Wibberley), review by Prof. L. Dudley Stamp, 612
- Ahnström, G., and Natarajan, A. T.: Chromosome Breakage induced by Electrolytically produced Free Radicals, 961

- Algrain, P.: Physics of Semiconductors (Occurrence of Oscillations in n-type Germanium and Indium Antimonide carrying a Current in a Longitudinal Magnetic Field), 633
- Ainsworth, Dr. G. C., and Balfour-Browne, Frances L. Guilelma Lister Centenary, 352
- Air Sustained, Localized, Pulsed-Microwave Discharge in (Charles W. Hamilton), 1098
- Air (Ground-Level): Concentration of some Fission Product Nuclides in (K. Edvarson and Kerstin Low), 125
- Air Ministry: Appointment of Hayne Constant as Scientific Adviser, 452
- Appointment of R. H. Weir as director of the National Gas Turbine Establishment, 452
- Reorganization of the Headquarters of the Meteorological Office, 707
- Retirement of Dr. J. M. Stagg as director of services of the Meteorological Office, 707
- Appointment of Dr. A. C. Best as director of services of the Meteorological Office, 707
- Air Ministry (Meteorological Office): The Observatories' Year Book, 1957 and 1958, 277
- Promotion of L. P. Smith to Senior Principal Scientific Officer, 281
- Air Pollutants: The Chemical Analysis of (Dr. Morris B. Jacobs), review by Dr. W. I. Stephen, 350
- Air Pollution: Atmospheric Diffusion and—Proceedings of a Symposium held at Oxford, 1958 (edited by Dr. F. N. Frenkiel and Prof. P. A. Sheppard), (Advances in Geophysics, Vol. 6), review by Dr. A. C. Best, 837
- The Chemistry of, review by Dr. W. I. Stephen, 350
- Aircraft: Applications of Electricity in (Joint Committee of the Institution of Electrical Engineers and the Royal Aeronautical Society to consider the), 453
- Aircraft Establishment (Royal): Promotion of L. G. Carpenter to Deputy Chief Scientific Officer, 280
- Promotion of D. G. King-Hale to Senior Principal Scientific Officer, 281
- Promotion of E. C. Maskell to Senior Principal Scientific Officer, 281
- Promotion of W. Watt to Senior Principal Scientific Officer, 281
- Aircraft and Guided Missiles: The Future of 'Electrics' and 'Electronics' in (Viscount Caldecote), 453
- Aitchison, Leslie: A History of Metals, review by Prof. F. C. Thompson, 263
- Aizawa, N.: Protease Inhibitor in Human Blood, 105
- Ajello, Franca, and others: Inhibitor of the Cytochrome Oxidase of Unfertilized Sea Urchin Eggs, 1195
- Akinetoplasmic Strain of *Trypanosoma evansi* produced by 'Prothidium' (Prof. H. N. Ray and M. N. Malhotra), 870
- Albatross (Wandering): Fact and Fiction on the Breeding of the (Dr. R. Carrick, K. Keith and Dr. A. M. Gwynn), 112
- Albert, Dr. A. (Johnson, Dr. P., and): Ultracentrifugation (Sedimentation Characteristics of Human Serum Macroglobulins), 635
- Alberta: Flora of (Prof. E. H. Moss), review by Gordon P. DeWolf, jun., 349
- Alberts, Bruce M., and others: Some Molecular Details of the Secondary Structure of Ribonucleic Acid, 98
- Albertsson, Dr. P. A.: Biological Structure and Function (New Technique for separating Macromolecules), 1160
- Albertsson, Dr. P. A. (Norrby, E. C. J., and): Concentration of Poliovirus by an Aqueous Polymer Two-Phase System, 1047
- Albino Rats ('Runted'): Serum Protein Abnormalities in (John S. Thompson and Clifford W. Gurney), 421
- Albula vulpes (L.): A Gular Place in (Prof. Orvar Nybelin), 78
- Albumin (Human Serum): Binding of Haematin by (Prof. H. N. Little and Prof. J. B. Neilands), 913

- Antiserum : Immuno-electrophoresis of Human Sera with, to Raben Growth Hormone (Dr. B. J. Boucher), 1025
- Aorta of Mice : Effects of Hexamethonium Bromide and β -Amino-Propionitrile on the Tensile Strength of the (A. W. J. Lykke, H. K. Müller and Prof. J. S. Robertson), 238
- Aortas (Atheromatous) : Histochemical Demonstration of some Hydrolytic Enzymes in (E. Levenon, Dr. J. Raekallio and Prof. U. Uotila), 677
- Apothecaries of London, Worshipful Society of : Honorary fellowship of the Faculty of the History of Medicine awarded to Sir Geoffrey Keynes and Prof. Owsei Temkin, 106
- Apparatus : 'Mechtronics' Electronic Teaching (Griffin and George, Ltd.), 22
- Scientific Instruments and (Institute of Physics and the Physical Society's Annual Exhibition of), 454, 1153 ; Handbook of, 1153
- Apparent Difference in the Renal Clearance of Calcium-45 and Calcium-40 in Rats (Dr. Robert C. Likins and Dr. Doris L. Craven), 592
- Apparent Resistance of *Rattus norvegicus* Berkenhout to Anticoagulant Poisons : Case of (C. Mary Boyle), 517
- Appetite in Dairy Cattle : Inhibition of, by certain Intermediate Metabolites (Dr. Donald R. Dowden and Prof. Don R. Jacobson), 148
- Apples : Fruit-Setting of, using Gibberellic Acid (R. M. Davison), 681
- Application of Electrostatic Power : Generation and (Centre National de la Recherche Scientifique International Colloquium on), 903
- Application of Laplace Transforms, review by Prof. A. H. M. Arnold, 969
- Application (Simultaneous), of Townsend and Streamer Theory (Dr. A. E. D. Heylen), 734
- Applications of Electricity in Aircraft (Joint Committee of the Institution of Electrical Engineers and the Royal Aeronautical Society to consider the), 453
- Applications of Electromagnetically Enriched Isotopes : Electromagnetic Isotope Separators and (J. Koch, R. H. V. M. Dawton, M. L. Smith and W. Walcher), review by Prof. E. H. S. Burhop, 262
- Applications (Geophysical) : Overvoltage Research and (edited by James R. Wait), review by P. Threadgold, 440
- Applied Bacteriology, Society for : Symposium on *Pseudomonas* and *Achromobacter*, 25
- Applied Chemistry : Reports of the Progress of, Vol. 42, 1957 (Society of Chemical Industry), review, 836
- Applied Chemistry (Pure and) : Twenty-first International Conference of, 193
- Eighteenth International Congress of, 193
- Applied Mathematics, review by Prof. L. S. Goddard, 89
- A Course in (Prof. Derek F. Lawden), review by Prof. T. A. A. Broad-bent, 840
- Applied Mechanics at Nottingham, 624
- Applied Mechanics : Advances in (edited by H. L. Dryden, Th. von Kármán and G. Kuerti), Vol. 6, review by Dr. Ian Proudman, 352
- Theoretical and (Indian Society of Theoretical and Applied Mechanics Sixth Congress on), 24
- Applied Mechanics (Theoretical and), Indian Society of : Sixth Congress on Theoretical and Applied Mechanics, 24
- Symposium on High Speed Computation Methods and Machines, 24
- Applied Mechanics (Theoretical and), International Union of, and the International Union of Geodesy and Geophysics : Symposium on Atmospheric Diffusion and Air Pollution (edited by Dr. F. N. Frenkiel and Prof. P. A. Sheppard), (Advances in Geophysics, Vol. 6), review by Dr. A. C. Best, 837
- Applied Microbiology, review by Dr. J. W. G. Porter, 812
- Advances in (edited by Wayne W. Umbreit), Vol. 2, review by Dr. J. W. G. Porter, 812
- Applied Palaeontology : Synthesis of, review by Prof. S. Simpson, 818
- Applied Physics (Pure and), International Union of : International Conference on the Physics of Semiconductors, 632
- Applied Physics (Pure and), International Union of, and others : International Conference on Physics Education, 107
- Applied Science in the University of London, 896
- Applied Scientific Research, Central Netherlands Organization for : Report by the Fibre Research Institute on Mounting Boards, 191
- Approach to the Steady State : Kinetics of Muscular Contraction—the (Dr. R. J. Podolsky), 666
- Approach (A New), to the Study of Thiamine Deficiency (Dr. C. C. Lang), 660
- Approaches to Science in the Primary School (edited for the New Education Fellowship by Evelyn Lawrence, Nathan Isaacs and Wyatt Rawson), review by B. J. G. Matland, 698
- Approaches (New), to Dynamical Astronomy, review by P. J. Message, 88
- Apterous Viviparae of *Myzus persicae* : Effect of Amputating Stylets of Mature (R. H. E. Bradley), 337
- Apurinic Acid : Reversible Behaviour of the Ultra-violet Irradiated Deoxyribonucleic Acid and its (Shih Yi Wang), 844
- Aquarium Behaviour and Breeding of *Hymenochirus* (R. Olsson and L. Österdahl), 869
- Aquatic Sports and Games : Some Sinhala Combative, Field and (Dr. P. E. P. Deraniyagala), 191
- Aqueous Polymer Two-Phase System : Concentration of Poliovirus by an (E. C. J. Norrby and Dr. P. A. Albertsson), 1047
- Aqueous Solution (Aerated) : Effect of X-Rays on Cytosine in (B. Ekert and Prof. R. Monier), 309
- Aqueous Solutions of Zinc Halides : Velocity of Ultrasonic Waves in (S. V. Subrahmanyam), 570
- Arable Land : Some Effects of Aldrin and DDT on the Soil Fauna of (C. A. Edwards and E. B. Dennis), 767
- D-Araboascorbic Acid : Production of, by *Penicillium* (Prof. T. Takahashi, M. Mitsumoto and H. Kayamori), 411
- Arbutin : Biosynthesis of, from some Phenylpropanoid Compounds in *Pyrus communis* (Prof. Sara K. Grisdale and Prof. G. H. N. Towers), 1130
- Archaeology (British), Council for : Booklist, 191
- Architects (Naval), Institution of, 1860-1960—an Historical Survey (K.-C. Barnaby), review by Prof. J. F. C. Conn, 177
- Architects (Naval), Royal Institution of : Royal Commissioners for the Exhibition of 1851 Postgraduate Scholarship in Naval Architecture (1960) awarded to B. S. Bowden, 106
- R.I.N.A. Scholarship in Naval Architecture (1960) awarded to M. A. Cubitt, 106
- Vickers-Armstrongs Scholarship in Naval Architecture (1960) awarded to Brian T. Procter, 106
- Architecture (Naval) : A Century of, review by Prof. J. F. C. Conn, 177
- Architecture (Roman) : First Century, review by Joan Liversidge, 5
- Archive for History of Exact Sciences, Vol. 1, No. 1, 1074
- Arca (Cold Cathode) : Submillimetre Waves by Harmonic Generation from (Dr. K. D. Froome), 43
- Arctic : Siberian—the Story of the Siberia Company (Jonas Lled), review by L. M. Forbes, 841
- Arctic Drifting Station Charlie : Telluric Current Micropulsations on (V. P. Hessler), 567
- Areas (Rural), and Small Communities : Water Supply for (Edmund G. Wagner and J. N. Lanox), review by Prof. W. G. V. Balchin, 825
- Arginine Vasotocin : Evidence for the Identity of Natrifrin, the Frog Water-Balance Principle and (Prof. Wilbur H. Sawyer), *erratum*, 454
- Argininosuccinase Activity in Brain Tissue (S. Tomlinson and R. G. Westall), 235
- Argus, G. R., and others : Calorimetry (An Ultrasensitive Thermistor Microcalorimeter), 788

- Astrophysique générale (J. C. Pecker et Prof. E. Schatzman), review by Prof. R. O. Redman, 348
- Atchley, Dr. William A. : Analysis of Human Leucocyte Deoxyribonucleohistone by Immuno-electrophoresis on Cellulose Acetate, 579
- Atheromatous Aortas : Histochemical Demonstration of some Hydrolytic Enzymes in (E. Levenon, Dr. J. Raekallio and Prof. U. Uotila), 677
- Atkin, R. H. : Classical Dynamics, review by Prof. G. J. Kynch, 838
- Atkinson, Dr. M. R., and Morton, Prof. R. K. : Synthesis of Nicotinic Acid Nucleotides, 58
- Atlantic Sea Shells : Canadian (E. L. Boufford), 1155
- Atlas : A New Lunar, review by Simone Daro Gossner, 88
- Atlas of European Birds (Prof. K. H. Voous), review by Dr. D. Lack, 1139
- Atlas de Paléogéographie (Prof. Henri Termier et Genevieve Termier), review by Prof. S. Simpson, 818
- Atmosphere : Sound Propagation in the (Acoustics Group of the Physical Society Symposium on), 992
- Atmosphere and the Sea in Motion—Scientific Contributions to the Rossby Memorial Volume (edited by Bert Bolin), review by Prof. P. A. Sheppard, 881
- Atmosphere (Upper) : Diurnal and Seasonal Density Variations in the (Earth Satellite Observations and the Upper Atmosphere), (Dr. W. Priestner, H. A. Martin and K. Kramp), 202
- Earth Satellite Observations and the—Temperature Inversion in the F-Layer (Dr. W. Priestner and H. A. Martin), 200 ; Diurnal and Seasonal Density Variations in the Upper Atmosphere (Dr. W. Priestner, H. A. Martin and K. Kramp), 202
- Atmospheres (70,000) : Pressure Dependence of Resistivity of Indium Antimonide to (H. A. Gebbie, P. L. Smith, I. G. Austin and J. H. King), 1095
- Atmospheric Cyclones (Southern), and the Whale Feeding Grounds in the Antarctic (Dr. C. W. Beklemishev), *erratum*, 106
- Atmospheric Diffusion and Air Pollution—Proceedings of a Symposium held at Oxford, 1958 (edited by Dr. F. N. Frenkiel and Prof. P. A. Sheppard), (Advances in Geophysics, Vol. 6), review by Dr. A. C. Best, 837
- Atmospheric Escape Layer : Physical Parameters of the (Dr. John J. Givarray), 804
- Atmospheric Pollution : The Investigation of (Atmospheric Pollution Research Committee of the Fuel Research Board), (Department of Scientific and Industrial Research), 626
- Atomfysik (Teoretisk), Nordisk Organization for : Second Annual Report (1958-59), 986
- Atomic Absorption Spectroscopy : Determination of Silver in Lead Concentrates by (B. S. Rawling, M. C. Greaves and M. D. Amos), 137
- Atomic Energy (Royal Scottish Museum Exhibition on), 193
- Atomic Energy in Australia : Peaceful Uses of—Proceedings of a Symposium on the (Sydney 1958), (Australian Atomic Energy Commission), review by A. S. White, 838
- Atomic Energy in Britain : A Guide to Information on (Central Office of Information), 1155
- Atomic Energy of Canada, Ltd. : Annual Report for 1959-60, 198
- Atomic Energy Agency (International) : Third Anniversary of the establishment of the, 21
- Election of A. D. McKnight as chairman of the Board of Governors, 367
- Appointment of Dr. Paul E. Gagnon as director of the Division of Exchange and Training of Scientists and Experts, 711
- Atomic Energy Authority (United Kingdom) : Promotion of Dr. T. E. Cranshaw to Senior Principal Scientific Officer, 281
- Promotion of R. D. Lowde (Atomic Energy Research Establishment) to Senior Principal Scientific Officer, 281
- Appointment of P. T. Fletcher as deputy managing director (General Management) in the Development and Engineering Group, 537
- Appointment of R. V. Moore as deputy managing director (Projects), in the Development and Engineering Group, 537
- Appointment of Dr. H. Kronberger as deputy managing director (Development) in the Development and Engineering Group, 537
- Appointment of S. Fawcett as director of reactor design in the Development and Engineering Group, 537
- Appointment of Dr. H. K. Hardy as director of fuel element development at the Research and Development Directorate at Risley, 537
- Appointment of F. W. Fenning as director of reactor technology at the Research and Development Directorate at Risley, 537
- Atomic Energy Commission (Australian) : Seventh Annual Report (1959), 110
- Proceedings of a Symposium on the Peaceful Uses of Atomic Energy in Australia, Sydney 1958, review by A. S. White, 838
- Atomic Energy Research Establishment (United Kingdom) : Formation of a Solid State Physics Division, 21
- Appointment of Dr. W. M. Lomer as head of the Solid State Physics Division, 21
- Appointment of Dr. W. C. Marshall as head of the Theoretical Physics Division, 21
- Promotion of R. D. Lowde to Senior Principal Scientific Officer, 281
- Solid State Physics Division to be organized into four research groups, 537
- Atomic Physics (Theoretical), in Norway, 986
- Atomic Polarizations of Chloro-, Bromo- and Iodo-benzene (Dr. H. H. Huang and Dr. E. P. A. Sullivan), 1104
- Atomic Weight of Silver : Mass-Spectrometer Investigation of the (W. R. Shields, D. N. Craig and V. H. Diebeler), 1156
- Atoms (Hydrogen) : Role of Ferrous Hydride in the Oxidation of Ferrous Ion by (Dr. G. Czapski and Dr. J. Jortner), 50
- Atropa belladonna Plants : Rate of Formation of Atropine in (J. R. Catch and E. A. Evans), 758
- Atropine in *Atropa belladonna* Plants : Rate of Formation of (J. R. Catch and E. A. Evans), 758

Attraction (Electrostatic), between a Liquid Surface and a Needle Height-Gauge (A. T. J. Hayward), 927

Atypical Spermiogenesis in *Thermobia domestica*, a Thysanuran Insect (Dr. S. R. Bawa), 1132

Aubel-Sadron, Dr. Geneviève, and others: Influence of a Quaternary Ammonium Salt on the Infectivity of Ribonucleic Acid from Tobacco Mosaic Virus, 689

Audio-genic Epilepsy (Post-traumatic) Prophylactic Treatment of (Dr. Z. Servit), 699

Auerbach, Prof. Victor H., and others: Elevated Serum Insulin associated with Laucine-induced Hypoglycaemia, 1036

Aukland, Dr. K., and Krog, Dr. J.: Renal Oxygen Tension, 671

Aurorae: The Outer Radiation Belt and (Harold Liemohn), 394

Austin, Dr. A. T.: The Action of Nitrous Acid on Aliphatic Amines, 1086

Austin, I. G., and others: Pressure Dependence of Resistivity of Indium Antimonide to 70,000 Atmospheres, 1095

Australia: Peaceful Uses of Atomic Energy in—Proceedings of a Symposium on the (Sydney 1958), (Australian Atomic Energy Commission), review by A. S. White, 838

Australia, Ecological Society of: Inauguration of the, 710

Australia (South): Occurrence of Hydromagnesite in Sediments in (Prof. A. R. Alderman and C. C. von der Borch), 931

Australian Atomic Energy Commission: Seventh Annual Report (1959), 110

Proceedings of a Symposium on the Peaceful Uses of Atomic Energy in Australia, Sydney 1958, review by A. S. White, 838

Australian Commonwealth Scientific and Industrial Research Organization: Collection of Australian Insects donated by Tarlton Rayment to the, 192

Division of Fisheries and Oceanography, Technical Paper No. 9, The Concentration of Plankton Pigments in Australian Waters (Dr. G. F. Humphrey), 199

Eleventh Annual Report (1958-59), 461

Appointment of F. N. Ratcliffe as assistant chief of the Division of Entomology in Canberra, 537

Appointment of Dr. H. E. Dadsell as chief of the Division of Forest Products, 988

Australian Insects: Tarlton Rayment's collection donated to the Australian Commonwealth Scientific and Industrial Research Organization, 192

Australian Mathematical Society: First Summer Research Institute to be held at Canberra, 711

Australian National Insect Collection, 192

Australian Region: Phytogeography of the (Dr. Nancy T. Burbidge), 544

Australian Waters: The Concentration of Plankton Pigments in (Dr. G. F. Humphrey), 199

Australites: Trace Elements in (Dr. S. R. Taylor and Maureen Sachs), 387

Auto-Antibodies against Antigen derived from Colon in the Microsomes of Regional Colonic Lymph Glands in Human Ulcerative Colitis (Dr. Peter Perlmann and Dr. Ove Broberger), 749

Automatic Control: Instrumentation, Data Processing and, review by P. H. Hammond, 827

Automatic Data-processing in University Administration, 710

Automatic Equipment for the Collection and Processing of Data from Geiger-Müller Counters (Dr. Richard Scott), 161

Automation: Ergonomics of (Problems of Progress in Industry, No. 8), (Department of Scientific and Industrial Research), 986

Progress in (edited by Dr. A. D. Booth), Vol. 1, review by P. H. Hammond, 827

Automation and Computation, British Conference on: Election of Officers, 625

Automation and Skill (E. R. F. W. Crossman), (Problems of Progress in Industry, No. 9), (Department of Scientific and Industrial Research), 986

Autonomy: Effects of, on Science and Technology, 21

Autotetraploidy (Colchi-) in *Adiantum capillus-veneris* (S. C. Verma and Dr. D. S. Loyal), 1210

Autotrophic Streptomyces: Knall-gas Reaction-linked Fixation of Labelled Carbon Dioxide in an (Ryuzi Kanai, Shigetoh Miyachi and Dr. Atsui Takamizaki), 873

Autumn Leaves (Detached): Auxin Control of Protein-Levels in (Daphne J. Osborne and Dr. Mary Hallaway), 240

Autumn Temperatures in the Red Sea Hills (Dr. L. Berry and Prof. J. L. Clouderley-Thompson), 843

Auxin Control of Protein-Levels in Detached Autumn Leaves (Daphne J. Osborne and Dr. Mary Hallaway), 240

Auxin-Type Chemicals: Morphological Reactions of Germinating Seeds as Criteria for the Plant Growth Regulating Activity of (J. Sudi, Gy. Josepovits and Gy. Matolcsy), 244

Availability of Strontium-90 in Soil: Changes with Time in the (Dr. Helen M. Squire), 518

Avery, Aamot G., and others: Blakeslee—the Genus *Datura*, review by R. D. Meikle, 834

Aviation Museum: The National, Ottawa (S. L. Roberts), 615

Avinur, P., and Nir, Dr. A.: Separation Factor of Tritiated Water in Fractional Distillation, 652

Awards: United Kingdom Postgraduate, 1960-62 (Association of Universities of the British Commonwealth), 784

Axolemma of the Giant Axon of the Squid: Equivalent Pore Radius in the (Dr. Ramundo Villegas and Flor V. Barnola), 762

Axon (Giant), of the Squid: Equivalent Pore Radius in the Axolemma of the (Dr. Ramundo Villegas and Flor V. Barnola), 762

Ayapin, Scopoletin and 6,7-Dimethoxycoumarin from *Dendrobium thyrsiflorum* (Reichb. f.), (T. C. Wrigley), 1108

Aykroyd, Dr. W. R.: Nutrition and Dietetics, review, 815

Ayres, Prof. J. C.: *Pseudomonas* and *Achromobacter*, 26

Azad, Prof. A. A.: Nuclear Science (Nuclear Science Programme in Iran), 541

Azzone, Dr. Giovanni Felice, and others: Energetic Aspects of the Mitochondrial Oxidation of Succinate, 552

BABIES (Negro). Genetic Aspects of Two Different Minor Haemoglobin Components found in Cord Blood Samples of (Prof. Titus H. J. Huismans), 589

Baboons (*Papio ursinus*): Importance of Insulin and of the Adrenal Cortex in determining the Toxicity in, to Human Anterior Pituitary (Prof. Joseph Gillman, Christine Gilbert and Edward Epstein), 861

Bach, Dr. S. J., and Hibbert, K. G.: Biochemistry of Bovine Ketosis—the Therapeutic Use of Fumarate and Cysteamine, 382

Backeberg, Curt: Die Cactaceae, Band 4, Ceroideae (Boreoceroeae), review, 835

Background (Radiation), under Water: Spectrum of (Gordon K. Riel, John P. Dolfs and Donald G. Simons), 266

Backus, Richard H. (Fejer, Andrew A., and): Porpoises and the Bow-Riding of Ships under Way, 700

Backward-Wave Oscillator: Operation of the (M. Y. Wong, Dr. G. D. Sims and Dr. I. M. Stephenson), 803

Bacon, Dr. G. E.: Thermal Motion in Crystals and Molecules, 369

Bacteria: The, a Treatise on Structure and Function (edited by I. C. Gunsalus and Roger Y. Stanier), Vol. 1, Structure, review by L. B. Quesnel, 259

Hexamine Synthesis by Cell-free Extracts of various (R. E. Strange and F. A. Dark), 741

Presence of Cell Walls like those of, in Rickettsiae (Dr. A. C. Allison and Dr. H. R. Perkins), 796

The Structure of, review by L. B. Quesnel, 259

Bacteria (Gram-negative): Action of 6-Aminopenicillanic Acid on (Dr. W. B. Hugo and A. D. Russell), 875

Bacteria (Rhizosphere): Chitin Breakdown of (Kecskés Mihály), 251

Bacteria (Soil): A Plate Method for Studying the Breakdown of Synthetic and Natural Silicates by (Dr. D. M. Webley, Dr. R. B. Duff and W. A. Mitchell), 766

Bacterial Anatomy: 'Oxidosomes' in (Prof. J. de Ley), 331

Bacterial Deoxyribonucleic Acid: Severe Distortion by S-Bromouracil of the Sequence Characteristics of a (Dr. Herman S. Shapiro and Prof. Erwin Chargaff), 62

Bacterial Genera *Pseudomonas* and *Achromobacter* (Dr. Eve Billing), 25

Bacterial Origin: Occurrence of D-Phenylalanine, D-Allothreonine and other D-Amino-Acids in Peptide-Lipids of (Dr. Miyoshi Ikawa, Dr. Edmond E. Snell and Dr. Edgar Lederer), 558

Bacterial Spores: Germination of, by Long-Chain Alkyl Amines (L. J. Rode and J. W. Foster), 1132

Bacterial Viruses: Plant and (edited by F. M. Burnet and W. M. Stanley), (The Viruses—Biochemical, Biological and Biophysical Properties, Vol. 2), review by F. C. Bawden, 882

Bactéries: La Sécrétion d'enzymes par les (Dr. M. R. Pollock), 627

Bacteriology at University College Hospital Medical School, London, 20

Bacteriology of the Mouth, review by Prof. R. B. Lucas, 811

Bacteriology (Applied), Society for: Symposium on *Pseudomonas* and *Achromobacter*, 25

Bacteriophage: *Brucella* (W. J. Brinley-Morgan, D. Kay and D. E. Bradley), 74

Baikie, A. G., and others: A Possible Specific Chromosome Abnormality in Human Chronic Myeloid Leukaemia, 1165

Bailey, Dr. A. R.: A Text-Book of Metallurgy, second edition, review, 264

Bailey, Dr. J. T. (Beattie, Dr. W. H., and): At the Tenth Canadian High Polymer Forum (Natural and Synthetic Macromolecules), 457

Bailey, R. V. C., and Gosse, J. S.: Hand-List of Darwin's Original Papers in the University Library, Cambridge, 1154

Bailey Bros. and Swinfen, Ltd.: Appointed distributing agents for the publications of the Palaeontographical Society, 24

Bainbridge, Dr. V.: Occurrence of *Calanoides carinatus* (Kroyer) in the Plankton of the Gulf of Guinea, 932

Bair, M. E., and others: Radio Detection of the Planet Saturn, 393

- Colitis (Human Ulcerative) : Auto-Antibodies against Antigen derived from Colon in the Microsomes of Regional Colonic Lymph Glands in (Dr. Peter Perlmann and Dr. Ove Broberger), 749
- Colitose (3-Deoxy-L-Fucose) as the Determinant Group : Preparation and Immunological Properties of an Artificial Antigen with (Dr. O. Luderitz, Prof. O. Westphal, Dr. A. M. Staub and Dr. L. Le Minor), 556
- Collagen : Hydrothermal Denaturation of (Prof. K. H. Gustavson), 419 ; (Dr. B. J. Rigby and Dr. J. B. Spikes), 420
- Hydroxyproline and the Shrinkage Temperature of (Dr. J. H. Bowes and Dr. J. A. Moss), 1120 ; (Dr. B. J. Rigby and Dr. J. D. Spikes), 1120
- Collecting and Communicating Scientific Information (Northampton College of Advanced Technology, London, Courses on), 1153
- Collection and Processing of Data from Geiger-Müller Counters : Automatic Equipment for the (Dr. Richard Scott), 161

- College of Aeronautics, Cranfield : Appointment of A. Rothwell as lecturer in aircraft design, 24
- Appointment of Dr. A. C. Smith as lecturer in mathematics, 24
- Comparative Efficiency of Indexing Systems (C. W. Cleverdon), 276
- College of Technology (City of Liverpool) : New Science Block (S. A. J. Parsons), 1076
- Colleges of Advanced Technology, 1137
- Collembola (Insecta) : Facultative Parthenogenesis in (H. E. Goto), 958
- Colletotrichum gossypii* South. B-nucleate and Tri-nucleate Conidia in (Colin Leakey), 685
- Collier, Dr. H. O. J. (Shorley, Patricia G., and) : Bradykinin—Direct Comparisons of the Synthetic Nonapeptide with Trypsin Bradykinin, 999
- Collingwood, Dr. E. F. : Appointed a member of the Medical Research Council, 193
- Collins, Dr. F. D. : Phospholipids containing Phosphate Triester Groups, 297
- Collins, R. B. : How Photography Works, review, 841
- Collins, Vera G. : *Pseudomonas* and *Achromobacter*, 27
- Collison, Dr. Roger : Ionic Conductances in Gels of Wheat Starch, 1105
- Colombani, J., and others : Difference between γ -Globulins fixed on the Platelets of Patients with Idiopathic Thrombocytopenic Purpura and of those suffering from Disseminated Lupus Erythematosus or a Panhaematocytopenia, 865
- Colon : Auto-Antibodies against Antigen derived from, in the Microsomes of Regional Colonic Lymph Glands in Human Ulcerative Colitis (Dr. Peter Perlmann and Dr. Ove Broberger), 749
- Colonial Development and Welfare Act : Return of Schemes made and of Loans approved (1959-1960), 1081
- Colonic Lymph Glands (Regional), in Human Ulcerative Colitis : Auto-Antibodies against Antigen derived from Colon in the Microsomes of (Dr. Peter Perlmann and Dr. Ove Broberger), 749
- Colonization (Fungal), of Seedling Roots of Leek and Broad Bean : A Comparison of Three Methods for the Assessment of (J. H. Clarke and Dr. D. Parkinson), 166
- Colorado (Northwest) : Fossil Mammalia from the Early Wasatchian Four Mile Fauna—Eocene of (Dr. M. C. McKenna), 200
- Colour (Two-) Image Synthesis : Tritanopia and (Arthur Karp), 40
- Colours on Jupiter : Some Experiments on Rice's Blue Material—(Prof. F. O. Rice and D. P. Cosgrave), 1023
- Columbite-bearing Soda Granite from South-east Uganda : Some Geochemical Aspects of a (Dr. O. von Knorring), 204
- Column (Trypsin) : A Water-insoluble Trypsin Derivative and its Use as a (Atara Bar-Eli and Prof. Ephraim Katchalski), 856
- Combative, Field and Aquatic Sports and Games : Some Sinhala (Dr. P. E. P. Deraniyagala), 191
- Commercial Organizations (Industrial and) : Survey of Information/Library Units In (C. W. Hanson), 21
- Commercial and Industrial Education, British Association for : Annual Conference, 1960 (Policy in Perspective), 257
- Commercial and Industrial Education, British Association for (East Midlands Group) : Ninth Annual Conference (Education for Survival), 257, 276
- Spring Conference (The Implications of the Crowther Report), 257, 276
- Common, Prof. R. H. : Proteins Induced in Plasma by Estrogens, 293
- Common-B Cross of *Schizophyllum commune* : Genetic Recombination in a (Yair Parag and John R. Raper), 765
- Commons, House of : Second reading of the Ministers of the Crown (Parliamentary Secretaries) Bill, 782
- Debate on Education, 967
- Second reading of the Rating and Valuation Bill, 1072
- Commonwealth : Universities of the, review, 4
- Commonwealth Advisory and Technical Service, 523
- Commonwealth Fund : Harkness Fellowships for 1961, 193
- Commonwealth Students in Britain : Science and Technology for, 897
- Commonwealth Universities Yearbook, 1960 (edited by J. F. Foster, assisted by T. Craig), thirty-seventh edition, review, 4
- Commonwealth (British), Association of Universities of the : Conference of the Universities of the United Kingdom—Report of Proceedings, 693
- Procedure for Admission of Students, 716
- United Kingdom Post-graduate Awards 1960-62, 784
- Commonwealth Bureau of Animal Breeding and Genetics : Technical Communication No. 14, The Indigenous Livestock of Eastern and Southern Africa (I. L. Mason and J. P. Maule), review by Sir John Hammond, 813
- Commonwealth Scientific and Industrial Research Organization (Australian) : Collection of Australian Insects donated by Tarlton Rayment to the, 192
- Division of Fisheries and Oceanography, Technical Paper No. 9, The Concentration of Plankton Pigments in Australian Waters (Dr. G. F. Humphrey), 199
- Eleventh Annual Report (1958-59), 461
- Appointment of F. N. Ratcliffe as assistant chief of the Division of Entomology in Canberra, 537
- Appointment of Dr. H. E. Dadsell as chief of the Division of Forest Products, 988
- Communicating Scientific Information : Collecting and (Northampton College of Advanced Technology, London, Courses on), 1153
- Communist China : The Sciences in (American Association for the Advancement of Science Symposium on), 24
- Communist Party of Great Britain : Public Conference on Education—18 Plus, 711
- Communities (Small) : Water Supplies for, review by Prof. W. G. V. Balchin, 825
- Water Supply for Rural Areas and (Edmund G. Wagner and J. N. Lanoix), review by Prof. W. G. V. Balchin, 825
- Comparative Anatomy (Prof. William Montagna), review by Prof. T. Nicol, 832
- Comparative Efficiency of Indexing Systems (C. W. Cleverdon), 276
- Comparative Endocrinology (Zoological Society of Japan Third International Symposium on), 784
- Comparative Pharmacology of some Psychotropic Drugs (E. Jacobson), 278
- Comparative Zoology, Museum of : Annual Report for 1957-58 (Harvard College), 22
- Comparison of Strains of *Streptomyces griseus* which produce Streptomycin and those which do not (G. Szabó, Prof. T. Vályi-Nagy, Gy. Barabás and G. Bássler), 428
- Comparison of Three Methods for the Assessment of Fungal Colonization of Seedling Roots of Leek and Broad Bean (J. H. Clarke and Dr. D. Parkinson), 166
- Comparisons (Direct), of the Synthetic Nonapeptide with Trypsin Bradykinin, (Bradykinin), (Patricia G. Shorley and Dr. H. O. J. Collier), 999
- Competition for Rural Land, review by Prof. L. Dudley Stamp, 612
- Complex of D-Amino-Acid Oxidase and Benzoate : Crystallization of the (Dr. Kunio Yagi, Takayuki Ozawa and Minoru Harada), 745
- Complex (Nitric Oxide) : Evidence for a, with Cupric Fluoride (R. T. M. Fraser), 738
- Complex Particles in Hevea Latex (Dr. W. A. Southern), 165
- Complexes of Polynucleotides with Spermine : Solubility of (Action of Spermine on Soluble Ribonucleic Acid and some Polynucleotides), (S. Lee Huang and Dr. G. Felsenfeld), 301
- Complexes (Cobalt), of the [Co(dga)X₃] Type : New Univalent (Dr. Nobumaki), 227
- Complexes (Copper (II) and Nickel (II)) : Absorption Spectra of (Dr. J. Császár and J. Balog), 402
- Complexes (Inorganic) : Spectra of Tetrahedral (S. Buffagni and T. M. Dunn), 937
- Complexes (Protein) : Enhanced Semiconductivity in (Semiconductivity in Proteins and Haemoglobin), (K. M. C. Davis, Prof. D. D. Eley and R. S. Smart), 724
- Component (A Lipid), of Murray Valley Encephalitis Virus (Dr. S. G. Anderson and G. L. Ada), 876
- Component Analysis : Structural Relations in (Dr. D. E. Barton and Dr. C. L. Mallows), 82
- Components ('Albumin'), of Human Muscle Extracts : Effect of Degeneration on the (B. P. Hughes), 1028
- Components (Two Different Minor Haemoglobin), found in Cord Blood Samples of Negro Babies : Genetic Aspects of (Prof. Titus H. J. Huisman), 589
- Components (Ultracentrifugal), in Human Plasminogen Preparations : Identification of (Prof. Sidney Shulman), 161
- Composite Response of Skin Homographs in the Rat (John Anderson), 679
- Composition : Soil (Filmstrips showing the Origin, Composition and Use of Soil, 4), (Marian Ray), 783
- Composition of the Free Fatty Acid Fraction in the Plasma of Human Arterial Blood (C. Chlouversakis and Dr. Peter Harris), 1111
- Composition (Base), of Ribonucleic Acid from Rat Mammary Gland during Pregnancy and Late Lactation (Dr. D. Y. Wang, T. F. Slater and Dr. A. L. Greenbaum), 320
- Composition (Milk), in the United Kingdom—Report of an Interdepartmental Committee, 1162
- Composition (Protein) : Correlation of Viral Ribonucleic Acid and (Prof. Martynas Yčas), 209
- Composition and Use of Soil : Filmstrips showing the Origin,—1, Rocks and Erosion ; 2, Plants and Decay ; 3, Soil Profiles ; 4, Soil Composition ; 5, Soil and Farming (Marian Ray), 783
- Compound (C₁₈H₁₆O₈), produced by the Fungus *Pestalotia ramulosa* : Ramulosin, a (Chester R. Benjamin and Frank H. Stodola), 662
- Compounds : Mechanisms of the Gas-phase Reactions of the Halogens and their (Faraday Society Informal Discussion on), 988
- Use of Chlorine in the Detection of, on Paper Chromatograms (C. G. Greig and Dr. D. H. Leaback), 310
- Compounds labelled with Radioactive Isotopes : Self-Decomposition of (Dr. R. J. Bayly and Dr. H. Weigel), 384
- Compounds (Aliphatic Carbonyl) : The Molecular Decomposition of (P. Borrell), 1002
- Compounds (Aromatic) : New Pathways in the Oxidative Metabolism of, by Micro-organisms (Dr. P. Dagley, Prof. W. Charles Evans and D. W. Ribbons), 560
- Reaction of, with a Chlorinated Coal and Aluminium Chloride (F. J. Pinchin), 848
- Compounds (Iodine) : Detection of, by Paper Chromatography (José M. Calvo and Luz Bascuro), 141
- Compounds (Metallic) : Systems with (Prof. Jean Timmermans), (The Physico-Chemical Constants of Binary Systems in Concentrated Solutions, Vol. 3), review by Dr. E. F. G. Herington, 819
- Compounds (Organic) : Identification of, by Gas Chromatography (Ian Brown), 1021
- Radiation-induced Carboxylation of—Formation and Reactions of the Carboxyl Radical Ion (Dr. G. Scholes, M. Simic and Prof. J. J. Weiss), 1019
- Compounds (Organocadmium) : True Reactivity of the (Dr. J. Kollonitsch), 140
- Compounds (Phenolic) : Stereochemistry of Natural (Plant Phenolics Group Meeting on), 367
- Compounds (Phenylpropanoid), in *Pyrus communis* : Biosynthesis of Arbutin from some (Prof. Sara K. Grisdale and Prof. G. H. N. Towers), 1130
- Computation : Analogue (International Association for Analog Computation third International Conference on), 367
- Computation, British Conference on Automation and : Election of Officers, 625
- Computation Methods and Machines : High Speed (Indian Society of Theoretical and Applied Mechanics Symposium on), 24
- Computation (Analog), International Association for : Third International Conference on Analogue Computation, 367
- Computer Engineering (edited by S. A. Lebedev), translated from the Russian by Jane Stuart ; translation edited by J. P. Cleave and F. A. Sowen, review by Dr. A. D. Booth, 970
- Computer Programmers : Selection and Training of (British Association for the Advancement of Science, Sub-section A* (Mathematics), Discussion on), 629
- Computer Service Centre at Woolwich Polytechnic, London, 708
- Computer-Generated Patterns : Binocular Depth Perception of (B. Julesz), 1156
- Computers : Analogue and Digital (consulting editor, Dr. M. G. Say ; advisory editors, A. C. D. Haley and W. E. Scott), review by Dr. A. D. Booth, 970
- Electronic (T. E. Ivall), second edition, review by Dr. A. D. Booth, 970

- Introduction to Electronic Analog (Prof John N Warfield), *review by* Dr. A. D. Booth, 970
- Computing Systems : Large Capacity Memory Techniques for (Information Systems Branch of the United States Office of Naval Research Symposium on), 627
- Conant, Dr James Bryant : The Child, the Parent and the State, 611
- Concentrated Solutions : The Physico-Chemical Constants of Binary Systems in (Prof. Jean Timmermans), Vol. 3, Systems with Metallic Compounds, *review by* Dr. E. F. G. Herington, 819
- Concentrates (Lead) : Determination of Silver in, by Atomic Absorption Spectroscopy (B. S. Rawling, M. C. Greaves and M. D. Amos), 137
- Concentrating Solutes of High Molecular Weight : A Method for (Dr. Per Flodin, Dr. B. Gelotte and Dr. J. Porath), 493
- Concentration of Circulating Tumour Cells : An Albumin Gradient Method for separating the Different White Cells of Blood, applied to the (A. I. Spriggs and R. F. Alexander), 863
- Concentration of some Fission Product Nuclides in Ground-Level Air (K. Edvarson and Kerstin Low), 125
- Concentration of Iodine-131 by the Submaxillary Gland of Mice : A Sexual Difference in the (J. L. Llach, J. H. Tramezzani and J. R. Cordero Funes), 1204
- Concentration of Plankton Pigments in Australian Waters (Dr G. F. Humphrey), 199
- Concentration of Poliovirus by an Aqueous Polymer Two-Phase System (E. C. J. Norrby and Dr. P. A. Albertsson), 1047
- Concerted Mechanism in Acid-Base Catalysis (Dr. F. J. C. Rossotti), 936
- Condensation Nuclear Techniques : Detection of Photochemical Oxidation of Sulphur Dioxide by (S. B. Dunham), 51
- Condition of the Animal : Catalase Activity of Mouse Liver and its relation to the (Dr. K. G. van Sanden and J. de Jong), 1116
- Conditions (Primeval Earth) : Synthesis of Macromolecules under Possible (A. T. Wilson), 1007
- Conductance Electrolytic (Prof Raymond M. Fuoss and Prof Filippo Accascina), *review by* Prof J. R. Partington, 1061
- Conductances (Ionic), in Gels of Wheat Starch (Dr. Roger Collison), 1105
- Conduction in Solids, *review by* Prof H. Jones, 821
- Conductivity (Electrical), of Strontium Oxide (M. J. Adams and L. Jacob), 130
- Cone (Pure-) Retina : Visual Pigment from a (Dr. H. J. A. Dartnall), 475
- Congo (West Belgian) : Glucose-6-phosphate Dehydrogenase Deficiency, Haptoglobin Groups, Blood Groups and Sickle Cell Trait in the Bantus of (Prof. J. Sonnet and Dr. J. L. Michaux), 504
- Congo Belge, Institut des Parcs Nationaux du : Exploration du Parc National Albert, Fasc. I, Introduction à l'Écologie des Ongulés du Parc National Albert (F. Bourlière et J. Verschuren), 997
- Conidia (Bi-nucleate and Tri-nucleate), in *Colletotrichum gossypii* South (Colin Leakey), 685
- Conifers (North American) : Parasitism of Dwarf Mistletoes on (Dr. Job Kuijt), 112
- Conn, Prof J. F. C. : A Century of Naval Architecture, *review*, 177
- Connective Tissue : Muscular Dystrophy in the Siamese Fighting Fish as an Aberration of the (Prof. A. Stolk), 751
- Connexion between P_C and the F Region (Dr. H. J. Duffus), 719
- Connor, R. : High Voltage Accelerators (Millimicrosecond Pulsing as compared with the 2- μ sec Pulse), 786
- Consden, Dr. R. : Studies on Agar Gel Electrophoresis, *review*, 8
- Chromatographic Reviews, *review*, 699
- Plasma Proteins, *review*, 816
- Conservation of Nature and Natural Resources, International Union for *Bulletin*, Vol. 9, Nos. 1-2, Report on the destruction of the Fauna of the Galapagos Islands (R. Leveque), 716
- Constant, Hayne : Appointed Scientific Adviser to the Air Ministry, 452, *work of*, 452
- Constants of Binary Systems, *review by* Dr. E. F. G. Herington, 819
- Constants (Acidic Dissociation), of Alcoholic Hydroxyls of Hydroxycarboxylic Acids—Tartaric Acid (B. Csizsar and P. Szarvas), 846
- Constants (Force-) : Invariance of Molecular 'Inverse' (Dr. S. J. Cyvin and Dr. N. B. Slater), 485
- Constants (Physico-Chemical), of Binary Systems in Concentrated Solutions (Prof. Jean Timmermans), Vol. 3, Systems with Metallic Compounds, *review by* Dr. E. F. G. Herington, 819
- Constants (Splitting), of several Well-known Free Radicals : Re-assessment of the Electron-spin Resonance (Dr. J. E. Bennett), 495
- Constants (Townsend Ionization), in *n*-Alkanes (O. H. LeBlanc, jun., and Dr. J. C. Devins), 219
- Constraints in the Determination of Active-Centre Topography (Marshall W. Nirenberg and William B. Jakoby), 747
- Construction (Roman), in Italy from Tiberius through the Flavians (Dr. Marion Elizabeth Blake), *review by* Joan Liversidge, 5
- Consulting Scientists, Association of : Election of Officers for 1960-61, 193
- Contaminant (Plasminogen), in Thrombin : Selective Inactivation of the (Dr. Gabor Markus and Dr. Clara M. Ambrus), 582
- Contamination (Radiological), of Materials and Reagents (Appointment by the International Commission on Radiological Units of a Sub-Committee on), 190
- Contemporary Japan—the Individual and the Group (Dr. Yoshiharu Scott Matsumoto), 111
- Conti, Dr. S. F., and Vlahnac, Dr. Wolf : Estimation of Magnesium and Purification of Chlorophyll from *Chlorobium thiosulphatophilum*, 489
- Continual Centrifugation : Growth of Mouse Femurs during (Prof. Charles C. Wunder, Stanley R. Briney, Melvin Kral and Charles Skaugstad), 151
- Continuous Portal Perfusion of Rats : Cannulation of Minute Mesenteric Veins for (Dr. Peggy L. E. Ross and Dr. A. M. Rappaport), 326
- Contraction (Muscular) : Kinetics of—the Approach to the Steady State (Dr. R. J. Podolsky), 666
- Contraction (Rhythmic), of Single Cultured Cardiac Muscle Cells : Specificity of the Effects of Cardiac Glycosides on the (Prof. Albert Wollenberger and Willi Halle), 1114
- Contribution of Rainwater to the Nutrient Economy of Soil in Northern Nigeria (E. Jones), 432
- Contributions (Pioneer), to Textile Technology : Chemistry in Scotland and its (Dr. A. Clow), 988
- Control : The Diseased Population, Epidemics and (edited by J. G. Horsfall and A. E. Dimond), (Plant Pathology, Vol. 3), *review by* W. C. Moore, 884
- Moiré Fringes for Measurement and (prepared by the National Physical Laboratory and the National Engineering Laboratory), 376
- Pests and their, *review by* F. H. Jacob, 1141
- Vegetable Diseases and their (Prof. Charles Chupp and Prof. Arden F. Sherf), *review by* Dr. W. G. Keyworth, 350
- Control of Infectious Diseases through Vaccination Programmes : European Technical Conference on the (Rabat, 1959), (World Health Organization, Publication No. 198), 1082
- Control of the Mind (Medical Center of the University of California Symposium on), 193
- Control of Plant Growth, *review by* Dr. D. J. Watson, 1060
- Control of Root Growth : Hormones and the (Prof. H. E. Street), 272
- Control Mechanism in the Synthesis of Induced β -Galactosidase : Enzyme Repression as the (Dr. G. Dénes), 852
- Control (Automatic) : Instrumentation, Data Processing and, *review by* P. H. Hammond, 827
- Control (Auxin), of Protein-Levels in Detached Autumn Leaves (Daphne J. Osborne and Dr. Mary Hallaway), 240
- Control (Chemical and Natural), of Pests (Dr. E. R. de Ong), *review by* F. H. Jacob, 1141
- Control (Nervous), from Primitive Organisms to Man : Evolution of—a Symposium organized by the Section on Medical Sciences of the American Association for the Advancement of Science, New York, 1956 (edited by Allan D. Bass), *review by* Prof. F. Gollia, 808
- Control (Pest) Research : Advances in (edited by R. L. Metcalf), Vol. 3, *review by* K. A. Lord, 834
- Control (Weed) : The Manatee—Ecology and Use for (W. H. L. Allsopp), 762
- Convection (Royal Meteorological Society Symposium on), 541
- Convection in Meteorology (Dr. R. P. Pearce), 541
- Conway, Dr. B. E. : At the Tenth Canadian High Polymer Forum (Natural and Synthetic Macromolecules), 457
- Cook, G. M. W., and others : A Salinocopeptide Liberated by Trypsin from the Human Erythrocyte, 1011
- Cook, Dr. James : Appointed a member of the Council for Scientific and Industrial Research, 193
- Cook, Dr. J. Gordon : Handbook of Textile Fibres, *review by* W. T. Astbury, 841
- Cook, J. J., and others : Radio Detection of the Planet Saturn, 393
- Cook, Dr. Maurice : Elected a Fellow of the Institute of Metals, 1075
- Coombs, Dr. M. M. : 2-Hydroxyoestrogens, 317
- Coons, Dr. Albert H., and others : The Harvey Lectures, Series 53, 1957-1958, *review by* Prof. J. Z. Young, 814
- Cooper, Prof. M. McG. : The Agricultural Research Council, 25
- Cooper, Dr. W. : At the Tenth Canadian High Polymer Forum (Natural and Synthetic Macromolecules), 457
- Co-operation between Schools and Universities in Educational Developments, 609
- Co-operation (International), for Oceanographic Research (Unesco Discussion on), 367
- Co-operation (International), in Research, 879
- Co-operation (International), Netherlands Universities Foundation for : Work of the, 709
- Co-ordination Chemistry (Symposium on, organized by the Czechoslovak Chemical Society and the Faculties of Inorganic Chemistry of the Charles University and the Technical University, and sponsored by the Czechoslovak Academy of Sciences), 715
- Co-ordination of Randomly Packed Spheres (Packing of Spheres), (Prof. J. D. Bernal and J. Mason), 910
- Co-ordination of Research, 277
- Cope, Arthur C., and others (edited by) : Organic Reactions, Vol. 10, *review by* Prof. John Read, 836

- Endless Frontier : Science, the (United States National Science Foundation Report), re-issue, 190
- Endo, Dr M. (Otsuka, Dr M., and) : Presynaptic Nature of Neuromuscular Depression in the Frog, 501
- Endocrinology : Comparative (Zoological Society of Japan Third International Symposium on), 784
- Endogenous Pyrogens (Exogenous and) : Inhibition of, by Lysozyme (Dr. P. Caselli and Dr. C. Callerio), 238
- Endogenous Substrates (Exogenous and) : Different Action of 2:4-Dinitrophenol on the Oxidation of, by Baker's Yeast (Prof. A. O. M. Stoppani, Dr. E. H. Ramos and I. Widuczynski), 1188
- Endt, Prof. P. M. : High Voltage Accelerators (Use of Proton- and Gamma-Rays in the Study of Nuclear Resonance-levels), 785
- Energetic Aspects of the Mitochondrial Oxidation of Succinate (Dr. Giovanni Felice Azzone, Dr. Lars Ernster and Dr. Martin Klingenberg), 552
- Energy in the Core of a Heated Tube : Radiative Transfer of (Sir K. S. Krishnan and R. Sundaram), 483
- Energy (High-) Electrons : Scattering of, by Protons (Prof. R. R. Wilson, Dr. K. Berkelman, Prof. J. M. Cassels and Dr. D. N. Olson), 94
- Energy (High-) Physics—Tenth Rochester Conference (E. M. Hafner), 778
- Engelbrecht, Dr. Elisabeth, and others : Biosynthesis of Damascenine in *Nigella damascena* L., 61
- Engineering : Computer (edited by S. A. Lebedev), translated from the Russian by Jane Stuart; translation edited by J. P. Cleave and F. A. Sowan, review by Dr. A. D. Booth, 970
- Mathematics in Physics and (I. Irving and N. Mullineux), review by Prof. L. S. Goddard, 89
- Engineering in Bone and Joint Surgery : Metals and (Prof. Charles Orville Bechtol, Prof. Albert Barnett Ferguson and Prof. Patrick Gowans Laing), review by Dr. E. G. C. Clarke, 818
- Engineering Laboratory (National) : Symposium on Flow Measurement in Closed Circuits, 786
- Engineering Study and Fundamental Research in Plastics : Fellowships for (Princeton University), 711
- Engineering (Biological) Society : First Meeting, 626
- Engineering (Electrical), at Edinburgh, 1072
- Engineering (Illuminating) Society : Election of Dr. W. S. Stiles as president for 1960-61, 193
- Engineers : Chemistry for (Edward Cartmell), review by Prof. J. R. Partington, 837
- Engineers (Electrical), Institution of, and the Royal Aeronautical Society : Formation of a Joint Committee to consider the Applications of Electricity in Aircraft, 453
- Engineers (Electronic) : Laplace Transforms for (James G. Holbrook), review by Prof. A. H. M. Arnold, 969
- Engineers (Gas), Institution of : Publication No. 578, The Choice of Subjects for Research and Development (Sir Harold Hartley), 1055
- Engineers (Mechanical), American Institute of : Third Reactive Metals Conference (1958), review by Prof. C. R. Tottle, 826
- Engineers (Nuclear), and Reactor Physicists : Training, 897
- Engineers (Radio), British Institution of : Convention on Radio Techniques and Space Research, 1156
- Engines : Jet Propulsion (edited by O. E. Lancaster), review by Dr. W. Cawood, 968
- Enhanced Semiconductivity in Protein Complexes (Semiconductivity in Proteins and Haemoglobin), (K. M. C. Davis, Prof. D. D. Eley and R. S. Smart), 724
- Ennor, Prof. A. H., and others : Synthesis of N-Phosphoryl-D- and L-Lombricine, 1026
- Enriched Isotopes (Electromagnetically) : Electromagnetic Isotope Separators and Applications of (J. Koch, R. H. V. M. Dawson, M. L. Smith and W. Walcher), review by Prof. E. H. S. Burhop, 262
- Enterobacteriaceae Strains on Media containing Ammonium : Sensitivity to Dihydrostreptomycin (of Fritz Ørskov and Ida Ørskov), 75
- Entomology : The Biospecies in (M. F. Claridge), 1172
- Entropy (Magnetic), in Ionic Crystals (Prof. J. W. Stout), 788
- Environment : Crop Production and (Dr. R. O. Whyte), new edition, review by Dr. D. J. Watson, 1060
- Environment (Cold) : An Adaptive Change in an Inbred Mouse Strain maintained in a (Dr. A. A. Barnett), 500
- Enzymatic Degradation of Deoxyribonucleic Acid into Sub-units (Giorgio Bernardi, Madeleine Champagne and Dr. Charles Sadron), 228
- Enzymatic Hydrolysis of Starch by Enzymes : Influence of the Surface of the Small Intestine on (Dr. A. Ugolev), 588
- Enzymatic Transformation of Dehydroascorbic Acid to Diketogulonic Acid (C. P. Tewari and Prof. P. S. Krishnan), 144
- Enzyme Repression as the Control Mechanism in the Synthesis of Induced β -Galactosidase (Dr. G. Dénès), 852
- Enzyme (Yeast) : Mechanism of Activation and Reduction of α -Aminoadipic Acid by (S. Sazisaka and Prof. K. Shimura), 1189
- Enzymes : Influence of the Surface of the Small Intestine on Enzymatic Hydrolysis of Starch by (Dr. A. Ugolev), 588
- Enzymes Histochemically Demonstrable in the Earliest Phase of Wound Healing (Dr. J. Raekallio), 234
- Enzymes (Hydrolytic), in Atheromatous Aortas : Histochemical Demonstration of some (E. Levenon, Dr. J. Raekallio and Prof. U. Uotila), 677
- Enzymes (Proteolytic) : A Method for the Direct Detection of, after Electrophoresis in Agar Gel (Dr. José Uriel), 853
- d'Enzymes (La Sécrétion), par les Bactéries (Dr. M. R. Pollock), 627
- Enzymes and Metabolism, review by Dr. Edwin C. Webb, 821
- Enzymic Indicator of Metabolic Pathways : Isocitrate as an (Dr. H. L. Kornberg), 488
- Enzymology and related Subjects of Biochemistry : Advances in (edited by F. F. Nord), Vol. 21, review by Dr. Edwin C. Webb, 821
- Eocene of Northwest Colorado : Fossil Mammalia from the Early Wasatchian Four Mile Fauna— (Dr. M. C. McKenna), 200
- Ephemers and Nautical Almanac for the Year 1961 : The Indian, review by D. H. Sadler, 8
- Ephrat-Elzur, Dr. Erela, and others : Transforming Activity of Deoxyribonucleic Acid labelled with 5-Bromouracil, 743
- Epidemic Goitre (Endemic and), in Italy, 284
- Epidemics and Control : The Diseased Population, (edited by J. G. Horsfall and A. E. Dimond), (Plant Pathology, Vol. 3), review by W. C. Moore, 884
- Epidermal Cell and the Metamorphosis of Insects (Prof. V. B. Wigglesworth), 358
- Epilepsy (Post-traumatic Audiogenic) : Prophylactic Treatment of (Dr. Z. Servit), 699
- Epiphytic Polyzoa : Effect of Extracts from Fucoids in promoting Settlement of (Dr. D. J. Crisp and G. B. Williams), 1206
- Epoxide Nature of the Carotenoid, Neoxanthin (Dr. Timothy H. Goldsmith and Dr. Norman I. Krinsky), 491
- Epstein, Edward, and others : Importance of Insulin and of the Adrenal Cortex in determining the Toxicity in Baboons (*Papio ursinus*) of Human Anterior Pituitary, 861
- Epstein, Dr. S. S. : Effect of some Benzimidazoles on a Vitamin B₁₂-requiring Alga, 143
- Equal Spheres : Packing of (Packing of Spheres), (Dr. G. David Scott), 908
- Equation for the Diffusion Potential : Derivation of an (Clifford S. Patlak), 944
- Equations (Hodgkin-Huxley) : Cardiac Action and Pacemaker Potentials based on the (D. Noble), 495
- Equator (Magnetic) : Effects of Diffusion of Electrons near the (Prof. V. C. A. Ferraro, J. E. C. Gliddon and P. C. Kendall), 1017
- Effects of Vertical Diffusion of Electrons near the (E. R. Schmerling), 133
- Equivalent Pore Radius in the Axolemma of the Giant Axon of the Squid (Dr. Raimundo Villegas and Flor V. Barnola), 762
- Equipment (Automatic), for the Collection and Processing of Data from Geiger-Müller Counters (Dr. Richard Scott), 161
- Erbium : Rapid Analysis of, by Neutron Activation followed by γ -Ray Spectrometry (Minoru Okada), 52
- Erdélyi, M., and others : Phosphorylation as a Factor in promoting the Crabtree Effect in the Amytal Ascites Sarcoma of White Mice, 857
- Ergonomics of Automation (Problems of Progress in Industry, No. 8), (Department of Scientific and Industrial Research), 986
- Ergonomics in Industry (Department of Scientific and Industrial Research Conference on), 633
- Ergot : Biogenesis of Lysergic Acid in (Elmore H. Taylor and Egil Ramstad), 494
- Ernster, Dr. Lars, and others : Oxidation of Human Haemoglobin by Vitamin K₃, 316
- Energetic Aspects of the Mitochondrial Oxidation of Succinate, 552
- Erosion : Rocks and (Filmstrips showing the Origin, Composition and Use of Soil, I), (Marian Ray), 783
- Erythematous (Disseminated Lupus), or a Panhaematocytopenia : Difference between γ -Globulins fixed on the Platelets of Patients with Idiopathic Thrombocytopenic Purpura and of those suffering from (Prof. J. Dausset, J. Colombani and M. Colin), 865
- Erythrocyte (Human) : A Sialomucopolysaccharide Liberated by Trypsin from the (G. M. W. Cook, Dr. D. H. Heard and Dr. G. V. F. Seaman), 1011
- Erythrocytes and Plasma Proteins in Mammals : Turnovers of (Dr. A. C. Allison), 37
- Esaki, L. : Physics of Semiconductors (Use of the Phenomenon of Quantum-mechanical Tunnelling as a Tool for the Study of some of the Fundamental Properties of Semiconductors), 633
- Escape Layer (Atmospheric) : Physical Parameters of the (Dr. John J. Gilvary), 804
- Escherichia coli : A Filterable Haemolysin from (Dr. R. Lovell and Dr. T. A. Rees), 755
- Malic Acid Synthesis in, and its Inhibition by Cocaine (S. G. Kalyanpur and Dr. E. O'F. Walsh), 939

- Housefly Larvae : Food of (Dr. Z. H. Levinson), 427
- Housemates : Ten Little (Prof. Karl von Frisch), review by F. H. Jacob, 1141
- Houssay, Prof. Bernardo A. : Organization of Scientific Research in Latin America, 1157
- Howard, Dr. H. W., and Wainwright, Dr. J. : Potato Virus M and Paracrinkle, 688
- Howe, Dr. Calderon, and others : Influenza Virus Sialidase, 251
- Howells, Dr. William : Mankind in the Making, review by Dr. J. S. Weiner, 807
- Howes, V. : Diamond Physics (High-temperature and High-vacuum Graphitization Experiments on Diamond), 368
- Howlett, Dr. J. : Selection and Training of Computer Programmers, 629
- Hoyle, Prof. Fred : The Nature of the Universe, new edition, review by Prof. Herbert Dingle, 1058
- Huang, Dr. H. H., and Sullivan, Dr. E. P. A. : Atomic Polarizations of Chloro-, Bromo- and Iodo-benzene, 1104
- Huang, S. Lee, and Felsenfeld, Dr. G. : Action of Spermine on Soluble Ribonucleic Acid and some Polynucleotides—Solubility of Complexes of Polynucleotides with Spermine, 301
- Hubbard, Dr. C. E., and Milne-Redhead, E. (edited by) : Flora of Tropical East Africa—Loganiaceae (E. A. Bruce and J. Lewis), review by J. P. M. Brennan, 1142
- Hubbard, Dr. Ruth, and Kropf, Dr. Allen : Regeneration of Visual Pigments from their Low-Temperature Photoproducts, 68
- Huber, Dr. W. : High Voltage Accelerators (Radiation Effects in Biological Systems), 786
- Hubner, K. (Shockley, W., and) : Physics of Semiconductors (An *n-p-n* Structure to demonstrate Phonon Drag on Electrons), 632
- Huddleston, W. : Awarded the first Ellis Medal of the Institution of Works Managers, 106
- Huffman (Hugh M.) Memorial Lecture (Prof. J. W. Stout), 788
- Huggins, Charles (Jull, John W., and) : Influence of Hyperthyroidism and of Thyroidectomy on Induced Mammary Cancer, 73
- Hughes, Dr. Arthur : The Father of Microscopy, review, 812
- Hughes, B. P. : Effect of Degeneration on the 'Albumin' Components of Human Muscle Extracts, 1028
- Hughes, D. E. R. : Production and Processing of Uranium, review, 348
- Hughes, I. : Appointed to a Research Fellowship in mathematics in the University of Glasgow, 988
- Hughes, Dr. R. B. (de Silva, Nihal N., and) : Effect of Tetracycline Antibiotics on the Proteolysis of Fish Muscle, 663
- Hughes, Walter L., and others : Absorption and Excretion of Copper in Mice, 150
- Hughes Medal of the Royal Society awarded to Dr. J. L. Pawsey, 536, 975
- Hugo, Dr. W. B., and Russell, A. D. : Action of 6-Aminopenicillanic Acid on Gram-negative Bacteria, 875
- Huisman, Prof. Titus H. J. : Genetic Aspects of Two Different Minor Haemoglobin Components found in Cord Blood Samples of Negro Babies, 569
- Human Amnion Cells infected with Psittacosis Virus : Cytochemical Changes in (Prof. Morris Pollard, Theodore J. Starr, Richard W. Moore and Yoh Tanami), 770
- Human Anterior Pituitary : Importance of Insulin and of the Adrenal Cortex in determining the Toxicity in Baboons (*Popio ursinus*) to (Prof. Joseph Gillman, Christine Gilbert and Edward Epstein), 861
- Human Arterial Blood : Composition of the Free Fatty Acid Fraction in the Plasma of (C. Chlouverakis and Dr. Peter Harris), 1111
- Human Beings : Measurements of Caesium-137 in, during 1958-59 (G. Maycock, Sheila W. Terry, J. Vennart and Dr. M. E. Wise), 355
- Human Blood : Protease Inhibitor in (N. Aizawa), 105
- Human Cell : Number of Chromosomes in the (Dr. Edward R. Pownser and Dr. Lawrence Berman), 1045
- Human Chromosomes : Nomenclature of, 278
- Human Chronic Myeloid Leukaemia : A Possible Specific Chromosome Abnormality in (A. G. Baikie, W. M. Court-Brown, Karin E. Buckton, D. G. Harnden, Patricia A. Jacobs and Isabel M. Tough), 1165
- Human Embryo Haemoglobin (Dr. Harry Zilliacus), 1202
- Human Erythrocyte : A Sialomucopolysaccharide Liberated by Trypsin from the (G. M. W. Cook, Dr. D. H. Heard and Dr. G. V. F. Seaman), 1011
- Human Gastric Mucosa and other Adult Mammalian Tissues : 5-Deoxycytidylic Acid-deaminating Activity in (Dino Guerritore, Vincenzo Rocchi and Andrea Setzu), 146
- Human Haemoglobin : Oxidation of, by Vitamin K₃ (Dr. Ove Broberger, Dr. Lars Ernster and Rolf Zetterstrom), 316
- Human Haemoglobins (Canine and) : Identification of the Recombinant Products of (Elizabeth A. Robinson and Dr. Harvey A. Itano), 798
- Human Leucocyte Deoxyribonucleohistone : Analysis of, by Immunoelectrophoresis on Cellulose Acetate (Dr. William A. Atchley), 579
- Human Muscle Extracts : Effect of Degeneration on the 'Albumin' Components of (B. P. Hughes), 1028
- Human Plasma collected during Labour : Spontaneous Plasma Kinin Formation in (Dr. Desirée A. J. Armstrong and Dr. J. W. Stewart), 1193
- Human Plasminogen Preparations : Identification of Ultracentrifugal Components in (Prof. Sidney Shulman), 161
- Human Platelet Phosphatide : The Half-life of (Dr. Charles M. Grossman, Alan M. MacEwan and James Dille), 950
- Human Ringworm : The Hedgehog as a Source of (Prof. Mary J. Marples and J. M. B. Smith), 867
- Human Sera with Antiserum : Immunoelectrophoresis of, to Raben Growth Hormone (Dr. B. J. Boucher), 1025
- Human Serum : Reduction of α -Ketobutyrate by (Dr. S. B. Rosalki and Dr. J. H. Wilkinson), 1110
- Human Serum Albumin : Binding of Haematin by (Prof. H. N. Little and Prof. J. B. Neilands), 913
- Human Serum Albumins : Separation of (M. D. Poulik, W. W. Zuelzer and R. Meyer), 506
- Human Society : Understanding (Prof. Walter Goldschmidt), review by Dr. F. Henriques, 351
- Human Sperm : Prolonged Survival of, in Chemically Defined Media at Room Temperatures (Prof. Charles Norman, Erwin Goldberg, I. D. Porterfield and C. A. Johnson), 760, erratum, 899
- Human Spermatozoa : Nuclear Structure of (C. van Duyn, jun.), 916 ; (Prof. Landrum B. Shettles), 918
- Human Sweat Glands : Intracellular Canals in (T. G. Scott), 158
- Human Synovial Fluid : Isolation of Hyaluronate from, by Zone Electrophoresis (Dr. David Hamerman and John Sandson), 1194
- Human Ulcerative Colitis : Auto-Antibodies against Antigen derived from Colon in the Microsome of Regional Colonic Lymph Glands in (Dr. Peter Perlmann and Dr. Ove Broberger), 749
- Humans (Normal) : Interrelations of Serum Protein Fractions in (Dr. C. J. Brackenridge), 154
- Humboldt University of Berlin : 150th Anniversary Celebrations, 1073
- Hume, Dr. H. Harold : Awarded a Gold Veitch Memorial Medal by the Royal Horticultural Society, 1156
- Hume-Rothery, Prof. W. : Elected an Honorary Member of the Institute of Metals, 1075
- Hume-Rothery, Prof. W., and others : A Determination of the Melting Point of Element 43 (Technetium), 48
- Humic Acids : Electron Paramagnetic Resonance Studies of Stable Free Radicals in Lignins and (Dr. R. W. Rex), 1185
- Humid Tropics : Termites in the (Unesco and the Zoological Survey of India Symposium on), 985
- Hummel, R. W., and Hearne, J. A. : The Nitrous Oxide Dosimeter, 734
- Huntten, D. M. : Recent Advances in Aeronomy (Spectra of Atmospheric Emissions), 713
- Humphrey, Dr. G. F. : The Concentration of Plankton Pigments in Australian Waters, 199
- Hurwicz, Prof. L., and others : Studies in Linear and Non-Linear Programming, review by Prof. L. S. Goddard, 6
- Husserl, Edmund (1859-1959) : Recueil commémoratif publié à l'occasion du Centenaire de la Naissance du Philosophe, review by F. I. G. Rawlins, 347
- Hutchinson, Dr. J. C. D. : Influence of Climate on Life (Life in the Tropics), 1080
- Hutchinson, J. S. M., and Robertson, Dr. Hamish : Effect of Season on the Follicle Stimulating Hormone and Luteinizing Hormone Potency of Sheep Anterior Pituitary Glands, 585
- Hutter, Dr. O. F., and Noble, D. : Rectifying Properties of Heart Muscle, 495
- Huus, Dr. T. : High Voltage Accelerators (Work on Coulomb Excitation), 785
- Hveding, D., and others : Caesium-137 Fall-out over Norway since September 1956, 1177
- Hvinden, T., and others : Caesium-137 Fall-out over Norway since September 1956, 1177

- Hyaluronate** Isolation of, from Human Synovial Fluid by Zone Electrophoresis (Dr. David Hamerman and John Sandson), 1194
- Hyaluronidase** : Tolerance to Maternal Skin Grafts in Rabbits induced by (Dr. Paul Nathan, Dr. Eduardo Gonzalez and Prof. Benjamin F. Miller), 77
- Hybrids** : Leaf-Shape in (Dr. R. Melville), 23
- Hybrids (Interspecific)**, of *Tilapia* (Dr. E. Trewavas and P. H. Greenwood), 868
- Hyde, H. A.** : Aerobiology and Medicine, 182
- Hydrated Haemoglobin** : Semiconductivity in (Semiconductivity in Proteins and Haemoglobin), (Prof. D. D. Eley and D. I. Spivey), 725
- Hydride (Ferrous)** : Role of, in the Oxidation of Ferrous Ion by Hydrogen Atoms (Dr. G. Czapski and Dr. J. Jortner), 50
- Hydrocarbons (Solid Aromatic)** : Shock Excitation of (Prof. R. W. Nicholls and M. D. Watson), 568
- Hydrodiction** The Water Net (Dr. M. A. Pocock), 545
- Hydrodynamics** : Theoretical (Prof. L. M. Milne-Thomson), fourth edition, review by Prof. L. Rosenhead, 87
- Hydrodynamics Research** (F. S. Burt), 454
- Hydroformylation** : Heterogeneous Catalysis in (Clyde L. Aldridge and Hans B. Jonassen), 404
- Hydrogarnet** : Formation of, by Chemical Reaction among Calcium Carbonate, Ammonium Chloride and some Silicates (Prof. Toshio Sudo, Satoru Ueda and Shigeki Iwamoto), 223
- Hydrogen in Jupiter** (C. C. Kieess, C. R. Corliss and Harriet K. Kieess), 278
- Hydrogen** (Heat of Adsorption of), on Tungsten at Elevated Temperatures (F. M. Page), 1021
- Hydrogen Atoms** : Role of Ferrous Hydride in the Oxidation of Ferrous Ion by (Dr. G. Czapski and Dr. J. Jortner), 50
- Hydrogen-bonding** in Calcium-deficient Hydroxyapatites (Dr. Aaron S. Posner, Joel M. Stutman and Ellis R. Lippincott), 486
- Hydrogen Bonds** in Deoxyribonucleic Acid of Phage T1 : Effects of Ultra-Violet Light on (Dr. Walter Sauerbier), 329
- Hydrogen Diffusion** in Mild Steels (P. K. Foster), 399
- Hydrogen Diffusion** in Water-accelerated Rolling Surface Fatigue (Dr. L. Grunberg, D. T. Jamieson, Dr. J. Raaskallio and Prof. U. Uotila), 1182
- Hydrogen-Ion Bombardment** : Effect of, on the Oxides of Aluminium and Magnesium (L. B. Griffiths), 43
- Hydrogen Peroxide (Activated)** : Formation of, by Irradiation of Water with α -Rays (Dr. P. Alexander and Dr. D. Rosen), 574
- Hydrolysis (Enzymatic)**, of Starch by Enzymes : Influence of the Surface of the Small Intestine on (Dr. A. Ugelstad), 588
- Hydrolytic Enzymes** in Atherosclerotic Aortas : Histochemical Demonstration of some (E. Levonen, Dr. J. Raaskallio and Prof. U. Uotila), 677
- Hydromagnetism** in Sediments in South Australia : Occurrence of (Prof. A. R. Alderman and C. C. von der Borch), 931
- Hydromagnetic Waves** : Evidence of Quasi-Perpendicular Propagation of, caused by Nuclear Explosions over Johnston Island (Prof. H. Maeda and T. Ondoh), 1018
- Hydrothermal Denaturation** of Collagen (Prof. K. H. Gustavson), 419 ; (Dr. B. J. Rigby and Dr. J. D. Spikes), 420
- Hydroxide (Aluminium)**, Phosphate and Soil-Water Systems : Aluminium Ions in (M. Raupach), 1049
- Hydroxyapatites (Calcium-deficient)** : Hydrogen-bonding in (Dr. Aaron S. Posner, Joel M. Stutman and Ellis R. Lippincott), 486
- Hydroxycarboxylic Acids** : Acidic Dissociation Constants of Alcoholic Hydroxyls of—Tartaric Acid (B. Csizsar and P. Szarvas), 846
- Hydroxylative Actions** of Quartz : Some Oxidative and—their Possible Relationship to the Development of Silicosis (L. W. Marasas and Dr. J. S. Harington), 1173
- Hydroxyls (Alcoholic)**, of Hydroxycarboxylic Acids—Tartaric Acid : Acidic Dissociation Constants of (B. Csizsar and P. Szarvas), 846
- Hydroxymethyl Purine Crystals** : Crystal Structure of 1-3-7-9 Tetra-methyluric Acid and the Molecular Packing in (P. De Santis, E. Giglio and Dr. A. M. Liquori), 46 ; (Dr. D. June Sutor), 47
- 2-Hydroxyoestrogens** (Dr. M. M. Coombs), 317
- Hydroxyproline** in Primary Cell Walls of Higher Plants (Derek T. A. Lamport and Dr. D. H. Northcote), 665
- Hydroxyproline** and the Shrinkage Temperature of Collagen (Dr. J. H. Bowes and Dr. J. A. Moss), 1120 ; (Dr. B. J. Rigby and Dr. J. D. Spikes), 1120
- 5-Hydroxytryptamine (Serotonin)**, in the Male Reproductive Tract of the Spiny Dogfish (Dr. T. Mann), 941
- Hygiene (Milk)** : Second Report of the Expert Committee on (United Nations, World Health Organization, Technical Report Series No. 197), 627
- Hymenochirus** : Aquarium Behaviour and Breeding of (R. Olsson and L. Osterdahl), 869
- Hyperconjugation** : Dipole Moment Data and (Ricardo Carvalho Ferreira), 848
- Hypercritical Region** : Nature of Fluids in the (J. R. Counsell and Prof. D. H. Everett), 576
- Hyperonic Flow Phenomena**, review by Dr. W. P. Jones, 822
- Hyperonic Flow Theory** (Wallace D. Hayes and Ronald F. Probststein), review by Dr. W. P. Jones, 822
- Hyperthyroidism** and of Thyroidectomy : Influence of, in Induced Mammary Cancer (John W. Jull and Charles Huggins), 73
- Hypervitaminosis A** : Vitamin A Acid and (J. N. Thompson and Dr. G. A. J. Pitt), 672
- Hypoglycaemia (Leucine-induced)** : Elevated Serum Insulin associated with (Angelo M. DiGeorge, Prof. Victor H. Auerbach and Dr. C. Charlton Mabry), 1036
- Hypoglycaemic Response** to Leucine in a Leucine-sensitive Man (Prof. W. J. H. Butterfield, M. J. Whiclow, P. H. Wright and L. I. Woolf), 70
- Hypothesis** : Origin of the Pacific Basin—a Meteorite Impact (E. R. Harrison), 1064
- Hypothetical Pathway** of Nitrogen Metabolism (Dr. Giovanni Costa), 549
- Identification of the Black Sub-Unit of the Crystallographic Model of Horse Haemoglobin** with the Valyl-Glutamyl Polypeptide Chain (Dr. David B. Smith and Dr. M. F. Perutz), 406
- Identification of Mode** in Low-Frequency Sweep Ionospheric Sounding, and Interference Patterns between Overlapping Echoes (A. Brunn-schweiler and H. N. Carlson), 217
- Identification of 19-Norandrostenedione** in Follicular Fluid (R. V. Short), 232
- Identification of Organic Compounds** by Gas Chromatography (Ian Brown), 1021
- Identification of the Recombinant Products of Canine and Human Haemoglobins** (Elizabeth A. Robinson and Dr. Harvey A. Itano), 798
- Identification of Ultracentrifugal Components** in Human Plasminogen Preparations (Prof. Sidney Shulman), 161
- Identity of Haemoglobin A₂** (C. J. Muller and Prof. J. H. P. Jonxis), 949
- Identity of Natriiferin**, the Frog Water-Balance Principle and Arginine Vasotocin : Evidence for the (Prof. Wilbur H. Sawyer, *erratum*, 454)
- Identity (Biological)**, with Natural Pure Trypsin Bradykinin : Synthetic Bradykinin, its, (Bradykinin), (Prof. H. Konzett and Dr. E. Sturmer), 998
- Idiocy (Infantile Amaurotic)** : Membranous Cytoplasmic Granules in (Prof. R. D. Terry and Prof. S. R. Korey), 1000
- Idiopathic Thrombocytopenic Purpura** : Difference between γ -Globulins fixed on the Platelets of Patients with, and of those suffering from Disseminated Lupus Erythematosus or a Panhaematocytopenia (Prof. J. Dausset, J. Colombani and M. Colin), 865
- Iguana iguana** : Diurnal Changes in the Topographical Distribution of Glycogen in the Brain of (Prof. A. Stolk), 751
- IGY Bulletin**, No. 37, July 1960, 191
- Ikawa, Dr. Miyoshi**, and others : Occurrence of D-Phenylalanine, D-Allo-threonine and other D-Amino-Acids in Peptide-Lipids of Bacterial Origin, 558
- Iles, Ronald B.** : External Sexual Differences and their Significance in *Mormyrus kannume* Forskal, 1775, 516
- Iijima, T. S.**, and others : Transduction in Actinomycetes, 245
- Illuminating Engineering Society** : Election of Dr. W. S. Stiles as president for 1960-61, 193
- Image (Electron Microscope Out-of-focus)**, of the Edge of a Crystal Lattice (Dr. Hatsujiro Hashimoto and Dr. Hiroshi Watanabe), 571
- Image Assessment** : Optical (Dr. N. S. Kapany), 1083
- Image Synthesis** : Tritanopia and Two-Colour (Arthur Karp), 40
- Immuno-electrophoresis on Cellulose Acetate** : Analysis of Human Leucocyte Deoxyribonucleohistone by (Dr. William A. Atchley), 579
- Immuno-electrophoresis of Human Sera** with Antiserum to Raben Growth Hormone (Dr. B. J. Boucher), 1025
- Immuno-Electrophoresis of Insulin-binding Antibodies** (Dr. H. Miller and G. Owen), 67
- Immunological Properties** : Preparation and, of an Artificial Antigen with Colitose (3-Deoxy-L-Fucose) as the Determinant Group (Dr. O. Luderitz, Prof. O. Westphal, Dr. A. M. Staub and Dr. L. Le Minor), 556
- Impairment of Strength of Quartz Glass** through Wetting by Liquids (K. H. Hiller), 132
- Imperial College of Science and Technology, London** : Appointment of Dr. J. S. Rowlinson to the University of London chair of chemical technology, 24, 189
- Appointment of M. J. Way to the readership in applied entomology, 24
- Appointment of Dr. B. J. Mason to the University of London chair of cloud physics, 539, 781
- Appointment of Prof. B. G. Neal to the University of London chair of applied science with special reference to engineering, 784, 896
- Code of Practice against Radiation Hazards, third edition, 984
- New Physics Department (N. C. Barford), 989
- Implements and Rock-Carvings** : Pre-History—899
- Implications of the Crowther Report** (Report on the Spring Conference of the British Association for Commercial and Industrial Education), 257, 276
- Importance of Insulin** and of the Adrenal Cortex in determining the Toxicity in Baboons (*Papio ursinus*) of Human Anterior Pituitary (Prof. Joseph Gillman, Christine Gilbert and Edward Epstein), 861
- Importance of the Tropics to Zoology** (British Association for the Advancement of Science, Section D (Zoology), Discussion on), 617
- Impossible Magnetic-Field Self-Patterning** (John H. Mathews), 651 ; (Dr. D. Midgley), 651
- Improved Method for Photographing Superficial Microbial Colonies** (Prof. G. Nogrady), 602
- Impulse (Nerve) Initiation** in a Pressure Receptor (Lorenzian Ampulla) : Mechanisms of (Werner R. Loewenstein), 1034
- Inactivation of Virus Haemagglutinins** by para-Chloromercuribenzoic Acid (F. E. Buckland), 768
- Inactivation (Selective)**, of the Plasminogen Contaminant in Thrombin (Dr. Gabor Markus and Dr. Clara M. Ambrus), 582
- Inactive A and B Chains (Separated and)** : Regeneration of Insulin Activity from the (Dr. G. H. Dixon and Dr. A. C. Wardlaw), 721
- Inbred Mouse Strain** maintained in a Cold Environment : An Adaptive Change in an (Dr. S. A. Barnett), 500
- Inbred Strains of Mice** : Haemoglobin Differences in (Dr. Helen M. Ranney, Dr. G. Marlowe Smith and Dr. Salome Gluecksohn-Waelsch), 212
- Incorporated Phosphorus-32** : Prevention of the Lethal Effect of the Decay of, by Growth at 45° (Dr. Ruth F. Hill), 412
- Incorporation of Amino-Acids** labelled with Carbon-14 in Nerve Proteins during Activity and Recovery (Mario Luxoro), 1119
- Incorporation of Caesium-137** from Nuclear Debris into the Biosphere (Dr. H. F. van Wijk and Dr. R. Braams), 951
- Incorporation of Thymidine** into Chromosomal Deoxyribonucleic Acid : An Effect of Tritiated Thymidine on the (Margarida Krause and Prof. W. Plaut), 511
- Incorporation (Early)**, of Sulphur-35 Sodium Sulphate in Plasma Proteins of Man (Dr. Bernard A. Sachs, Edward Siegel and Joseph V. Marino), 1125
- Increase in Level of Chlorophyll** in *Pisum sativum* L. (Effect of Polyvinyl Alcohol on Chlorophyll and Haem in *Chlorella* and *Tandipes*), (Dr. Leopold Rejmak, Dr. Henryk Fr. Nowak and Bazyli Czeczuga), 120
- Ice** : Low-Temperature Forms of, as studied by X-Ray Diffraction (L. G. Dowell and A. P. Rinfret), 1144
- Ice (Protonated)** : Direct Measurements of Proton Mobilities in (F. Hein-mets), 925

- Increasing the Effectiveness of Western Science (Science Committee of NATO), 880
- Indexing Systems Comparative Efficiency of (C. W. Cleverdon), 276
- India : Jute in (Dr. B. C. Kundu, K. C. Basak and Dr. P. B. Sarkar), review by Dr. H. P. Stout, 971
- Light Metal Industry in (National Metallurgical Laboratory, Jamshedpur, Symposium on), 1075
- India (Central) : Caste and Kinship in (Dr. Adrian C. Mayer), review by G. I. Jones, 351
- Sociology of Caste in, review by G. I. Jones, 351
- Indian Anthropology (compiled by J. M. Kanitkar; edited, revised and enlarged by D. L. Banerjee and A. K. Ohdekar), (A Bibliography of Indology, Vol. 1), 278
- Indian Council of Agricultural Research : *Indian Potato Journal*, 105
- Indian Ephemeris and Nautical Almanac for the Year 1961, review by D. H. Sadler, 8
- Indian Potato Journal* (Indian Council of Agricultural Research), 105
- Indian Research on Jute, review by Dr. H. P. Stout, 971
- Indian Society of Theoretical and Applied Mechanics : Sixth Congress on Theoretical and Applied Mechanics, 24
- Symposium on High Speed Computation Methods and Machines, 24
- Indian Venture : Coal Science—an, review by Dr. I. G. C. Dryden, 1140
- Indicator (Enzymic), of Metabolic Pathways : *isocitratase* as an (Dr. H. L. Kornberg), 488
- India (West) Soil Survey in the (Prof. L. Dudley Stamp), 109
- Unidentified Earth Tremors in Dominica, (G. R. Robson and K. G. Barr), 306
- Indigenous Livestock of Eastern and Southern Africa (I. L. Mason and J. P. Maule), review by Sir John Hammond, 813
- Indigenous Populations (Aboriginal and) : Blood Groups of Selected (Prof. John Buettner-Janusch, Henry Gershowitz, Leopold J. Pospisil and Peter Wilson), 153
- Indium Antimonide : Pressure Dependence of Resistivity, of, to 70,000 Atmospheres (H. A. Gebbie, P. L. Smith, I. G. Austin and J. H. King), 1095
- Individual : The Ageing, review by Prof. L. S. Hearnshaw, 614
- Handbook of Aging and the—Psychological and Biological Aspects (edited by Dr. James E. Birren), review by Prof. L. S. Hearnshaw, 614
- Individual and the Group : Contemporary Japan—the (Dr. Yoshiharu Scott Matsumoto), 111
- Indology : A Bibliography of, Vol. 1, *Indian Anthropology* (compiled by J. M. Kanitkar; edited, revised and enlarged by D. L. Banerjee and A. K. Ohdekar), 278
- Induced β -Galactosidase : Enzyme Repression as the Control Mechanism in the Synthesis of (Dr. G. Dénes), 852
- Induced Mammary Cancer : Influence of Hyperthyroidism and of Thyroidectomy on (John W. Jull and Charles Huggins), 73
- Inducible, Reactive Materials resembling Antibody : Detection in Invertebrates of (John H. Phillips and Benjamin J. Yardley), 728
- Induction of Tumours by Polyoma in Adult Hamsters (Dr. V. Defendi), 508
- Induction-heated Vacuum Furnace : Elimination of a Glow Discharge In an (J. P. Burden), 221
- Industrial Biological Research Association : British, 1072
- Industrial Education (Commercial and), British Association for : Annual Conference, 1960 (Policy in Perspective), 257
- Industrial Education (Commercial and), British Association for (East Midlands Group) : Ninth Annual Conference (Education for Survival), 257, 276
- Spring Conference (The Implications of the Crowther Report), 257, 276
- Industrial Health : Annual Report of the Chief Inspector of Factories on, 1959 (Ministry of Labour and National Service), 460, 717
- Industrial Research Associations in the Government Scheme : Research for Industry 1959—a Report on Work done by (Department of Scientific and Industrial Research), 195
- Industrial Research and Development, 1055
- Industrial Society : Education for an, 257
- Industrial Waste : Afforestation of (British Association for the Advancement of Science, Section K* (Forestry), Symposium on), 11
- Industrial and Commercial Organizations : Survey of Information/Library Units in (C. W. Hanson), 21
- Industry : Education in, 276
- Ergonomics in (Department of Scientific and Industrial Research Conference on), 633
- Powders in (Surface Activity Group of the Society of Chemical Industry Symposium on), 1161
- Problems of Progress in, No. 8, *Ergonomics of Automation*, 986; No. 9, *Automation and Skill* (E. R. F. W. Crossman), 986 (Department of Scientific and Industrial Research)
- Safety Propaganda in (Dr. S. Laner and R. G. Sell), 898
- Industry 1959 : Research for—a Report on Work done by Industrial Research Associations in the Government Scheme (Department of Scientific and Industrial Research), 195
- Industry (Pharmaceutical), and Rauwolfia : Plant Resources of the Middle East and South Asia for the (Government of Pakistan, the Unesco Middle East Science Co-operation Office and the Unesco South Asia Science Co-operation Office Symposium on), 539
- Industry (Russian) The Red Executive—a Study of the Organization Man in (Dr. David Granick), review by T. H. Hawkins, 7
- Industry (Scientific Instrument) : Careers in the (Scientific Instrument Manufacturers' Association), 1155
- Industry (United Kingdom) : Overseas Trainees in (Federation of British Industries), 897
- Inert Particles : Rate of Passage of, through the Alimentary Tract of the Cow (R. C. Campling and M. Freer), 670
- Inexcitability (Electrical), of the Synaptic Membrane in the Frog Skeletal Muscle Fibre (Prof. Robert Werman), 149
- Infant Monkeys : Phenylketonuria in (Prof. Harry A. Waisman, Hwa L. Wang, Gail Palmer and Prof. Harry F. Harlow), 1124
- Infantile Amaurotic Idiocy : Membranous Cytoplasmic Granules in (Prof. R. D. Terry and Prof. S. R. Korey), 1000
- Infection : Polyoma Virus in Syrian Hamsters—a Non-communicable (Prof. Bernard Roizman and Philip R. Roane, jun.), 1134
- Infection (Food-borne), and Intoxication : Food Poisoning, (Elliot B. Dewberry), fourth edition, review by Dr. F. H. Banfield, 836
- Infection (*Leptospira pomona*), in an Eastern Red Fox (*Vulpes fulva fulva*), (Lawrence G. Clark, Joseph I. Kresse, Prof. Robert R. Marshak and Charles J. Hollister), 1040
- Infectious Diseases : European Technical Conference on the Control of, through Vaccination Programmes (Rabat, 1959), (World Health Organization, Publication No. 198), 1082
- Infectious Variegation Virus of Citrus : Mechanical Transmission of the (Dr. T. J. Grant and Dr. M. K. Corbett), 519
- Infectivity of Newcastle Disease Virus Nucleic Acid Preparations : Failure to Demonstrate (Prof. A. A. Benedict, Donald Lee and Barbara West), 911
- Infectivity of Ribonucleic Acid from Tobacco Mosaic Virus : Influence of a Quaternary Ammonium Salt on the (Leon Hirth, Geneviève Lebeurier, Dr. Geneviève Aubel-Sadron, Gisèle Beck, Jean-Pierre Ebel and Paul Horn), 689
- Infinite Games : The Theory of (Samuel Karlin), (Mathematical Methods and Theory in Games, Programming and Economics, Vol. 2), review by Prof. L. S. Goddard, 825
- Inflamed Capillaries : Leucocyte Emigration from (Dr. J. R. Williamson and Dr. J. W. Grisham), 1203
- Inflation of the Neck Pouch of the Marabou Stork (Malcolm J. Coe), 598
- Influence of Amino Triazole on the Chloroplast Pigments of Wheat Seedlings (Prof. Frederick T. Wolf), 164
- Influence of Climate on Life (International Society for Bioclimatology and Biometeorology Second International Bioclimatological Congress), 1080
- Influence of Hyperthyroidism and of Thyroidectomy on Induced Mammary Cancer (John W. Jull and Charles Huggins), 73
- Influence of Light from an Infra-red Bulb on the Mutagenic Effect of Colchicine on *Sorghum* (Clifford J. Franzke, Mary E. Sanders and James G. Ross), 242
- Influence of Light Intensity on the Redox Potential in Leaves in cases of Iron-induced Chlorosis (L. Heras), 335
- Influence of Moisture on the Spontaneous Heating of Coal (Dr. J. B. Stott), 54
- Influence of the Organic Matrix on Crystal Type in Molluscs (Prof. Norimitsu Watabe and Karl M. Wilbur), 334
- Influence of Pteridines on the Production of Vitamin B₁₂ by Trypanosomid Flagellates (Helene A. Nathan, Herman Baker and Oscar Frank), 35
- Influence of a Quaternary Ammonium Salt on the Infectivity of Ribonucleic Acid from Tobacco Mosaic Virus (Leon Hirth, Geneviève Lebeurier, Dr. Geneviève Aubel-Sadron, Gisèle Beck, Jean-Pierre Ebel and Paul Horn), 689
- Influence of the Surface of the Small Intestine on Enzymatic Hydrolysis of Starch by Enzymes (Dr. A. Ugolev), 588
- Influence of Thyroid on Radiophosphorus Metabolism in Fish (Dr. P. N. Srivastava), 512
- Influence of Tranquillizing Drugs on Phagocytosis *in vivo* (Prof. Leo Greenberg and James W. Ingalls), 588

 Safety of, in Factories, 460
 People and Parrots, review by P. R. F. Clarke, 814
 Pepler, W. J., and Loubser, E.: Histochemical Demonstration of the Mode of Action of the Alkaloid in Mussel Poisoning, 860
 Pepper (Black), *Piper nigrum* L., in Sarawak: Toxicity of Aluminium to (P. W. F. de Waard and C. D. Sutton), 1129
 Peptides (Phosphorylated): Tryptic and Phosphatase Action on certain Synthetic (Dr. D. Theodoropoulos, Prof. J. Gazopoulos and I. Souclieris), 489
 Peptides (Synthetic), of a Protease from Rabbit Spleen: Action of some (T. Webb and Cl. Lapresle), 66
 Peptido-Lipids of Bacterial Origin: Occurrence of D-Phenylalanine, D-Allothreonine and other D-Amino-Acids in (Dr. Miyoshi Ikawa, Dr. Esmond E. Snell and Dr. Edgar Lederer), 558
 Peptone: A New Cyclic Dipeptide from (Prof. Takuo Kosuge and Hiroko Kamiya), 1112
 Pepps, J., and others: Misinterpretation of an Agar-Gel Precipitation Pattern, 685
 Perception of Distance in Animal Echo-Location (Jan Nordmark), 1009
 Perception (Binocular Depth), of Computer-Generated Patterns (B. Julesz), 1156
 Percival, Dr. M. S. (Hawkins, R. P., and): Pollination by Insects, 902
 Perelman, A. I.: Geochemical Landscape, 23
 Perfusion (Continuous Portal), of Rats: Cannulation of Minute Mesenteric Veins for (Dr. Peggy L. E. Ross and Dr. A. M. Rappaport), 326
 Perils of Leadership in Science (Sir Lindor Brown), 174
 Periodical Publications (Scientific): Cost of (M. W. Perrin), 1052; (D. B. Baker), 1052
 Periodicals in the Chemical Society Library (Chemical Society), 1156
 Periodicals (British Books and), for Use Overseas, 904
 Periods of Cold Storage: Changes in Amounts of Organic Acids in Citrus Leaves during (Dr. H. T. Freebairn), 243
 ('Peripoleis') Interaction of Macrophages and Lymphocytes after Skin Homografting or Challenge with Soluble Antigens (J. A. Sharp and Dr. R. G. Burwell), 474
 Perkin Centenary Trust: Awards for 1961-62, 538
 Perkins, Dr. D. H., and others: The Study of Elementary Particles by the Photographic Method, review by Prof. G. D. Rochester, 175
 Perkins, Dr. H. R. (Allison, Dr. A. C., and): Presence of Cell Walls like those of Bacteria in Rickettsiae, 796
 Parkins, J. F.: Appointed deputy keeper in the Department of Entomology in the British Museum (Natural History), 1153; work of, 1153
 Perlmann, Dr. Peter, and Broberger, Dr. Ove: Auto-Antibodies against Antigen derived from Colon in the Microsomes of Regional Colonic Lymph Glands in Human Ulcerative Colitis, 749
 Permanent Gas Analysis: An Ultra-sensitive Ionization Detector for (R. Berry), 578
 Permanganates (Thermally Decomposed): X-Ray Diffraction Studies of (P. J. Herley and Dr. E. G. Prout), 717
 Permeability in Living Membranes: Mechanism of Change in (Dr. A. M. Shanes), 1209
 Peroxide (Hydrogen): Formation of Activated, by Irradiation of Water with α -Rays (Dr. P. Alexander and Dr. D. Rosen), 574
 Perpendicular (Quasi-) Propagation of Hydromagnetic Waves: Evidence of, caused by Nuclear Explosions over Johnston Island (Prof. H. Maeda and T. Ondoh), 1018
 Perrin, M. W.: Cost of Scientific Periodical Publications, 1052
 Perry, B. J., and others: A New Synthetic Route to Alkylphosphonous Dichlorides, 227
 Personal Responsibility: Popular Culture and (National Union of Teachers Conference on), 24
 Perspective: Policy in (British Association for Commercial and Industrial Education Annual Conference), 257
 Perutz, Dr. M. F. (Smith, Dr. David B., and): Identification of the Black Sub-Unit of the Crystallographic Model of Horse Haemoglobin with the Valyl-Glutaminyl Polypeptide Chain, 406
 Peasall, Dr. N.: Appointed to a Fellowship in physical metallurgy at the University of Birmingham, 539
 Pest Control Research: Advances in (edited by R. L. Metcalf), Vol. 3, review by K. A. Lord, 834
 Peters, Prof. R. H. (Hearle, Dr. J. W. S., and): Moisture in Textiles, review by Dr. J. W. Bell, 823
Pestalotia ramulosa (Fungus): Ramulosin, a $C_{18}H_{14}O_2$ Compound produced by the (Chester R. Benjamin and Frank H. Stodola), 662
 Pests: Chemical and Natural Control of (Dr. E. R. de Oñg), review by F. H. Jacob, 1141
 Horticultural (G. Fox Wilson), new edition, revised by Dr. P. Becker, review by F. H. Jacob, 1141
 Pests and their Control, review by F. H. Jacob, 1141
 Pests of Standing Crops (British Association for the Advancement of Science, Section D (Zoology), Discussion on), 360
 Peterson, Frederick A.: Ancient Mexico, an Introduction to the Pre-Hispanic Cultures, review by Dr. G. H. S. Bushnell, 90
 Petley, B. W.: Appointed to a Fellowship in physics at the University of Birmingham, 539
 Pflanzen: Grundzüge der Histogenese Hoherer (Prof. Dr. Hermann von Guttenberg), I, Die Angiospermen (Handbuch der Pflanzenanatomie, zweite Auflage, herausgegeben von Prof. Dr. W. Zimmermann und Prof. P. G. Ozenda, Band 8, Teil 3), review by Dr. F. A. L. Clowes, 1141
 Pflanzenanatomie: Handbuch der, zweite Auflage, herausgegeben von Prof. Dr. W. Zimmermann und Prof. P. G. Ozenda, Band 8, Teil 3, Grundzüge der Histogenese Hoherer Pflanzen (Prof. Dr. Hermann von Guttenberg), I, Die Angiospermen, review by Dr. F. A. L. Clowes, 1141
 Pflanzenphysiologie (Prof. Henrik Lundegårdh), review by Prof. W. O. James, 811
 Pflanzenstoffe (organischen), exclusive Alkaloide: Konstitution und Vorkommen der (Dr. Walter Karrer), review by Dr. T. G. Halsall, 440
 Phaal, C. (Evans, T., and): Diamond Physics (Study of Graphitization), 368
 Phase T1: Effects of Ultra-Violet Light on Hydrogen Bonds in Deoxyribonucleic Acid (Dr. Walter Sauerbier), 329
 Reaction of Formaldehyde with Deoxyribonucleic Acid in (Dr. Walter Sauerbier), 327
 Phagocytosis in vivo: Influence of Tranquillizing Drugs on (Prof. Leo Greenberg and James W. Ingalls), 588
 Pharmaceutical Codex 1959: British, review by Prof. J. H. Gaddum, 836
 Pharmaceutical Conference (British): Election of Dr. D. C. Garratt as chairman for 1960-61, 24
 Pharmaceutical Industry and Rauwolfia: Plant Resources of the Middle East and South Asia for the (Government of Pakistan, the Unesco Middle East Science Co-operation Office and the Unesco South Asia Science Co-operation Office Symposium on), 539
 Pharmacology (Comparative), of some Psychotropic Drugs (E. Jacobson), 278
 Phase (Earliest), of Wound Healing: Enzymes Histochemically Demonstrable in the (Dr. J. Raekallio), 234
 Phase (Water), of Gelatin Gels: Proton Magnetic Resonance of the (Erik Odeblad), 579
 Phase Diagram of the System Vanadium Pentoxide-Boron Trioxide (B. Nádor), 139
 Phenazine Methosulphate as a Mediator in the Oxidation of Pyruvate by Pyruvate Decarboxylase from Brewer's Yeast (Dr. Helmut Holzer and R. M. M. Crawford), 410
 Phenaziniumes: The—A Possible Explanation of Anomalies associated with Neutral Red (Prof. Donald L. Vivian), 746
 Phenolic Compounds: Stereochemistry of Natural (Plant Phenolics Group Meeting on), 367
 Phenolics Group (Plant): Meeting on the Stereochemistry of Natural Phenolic Compounds, 367
 Phenomena: Hyperosmotic Flow, review by Dr. W. P. Jones, 822
 Phenomena (The Critical), between Solids and Fluids (Dr. Kazuo Furukawa), 569
 Phenomena (Ionization), in Gases (Verband Deutscher Physikalischer Gesellschaften Fifth International Conference on), 1075
 Phenomena (Sub-Atomic): The Study of, by the Nuclear Emulsion, review by Prof. G. D. Rochester, 175
 Phenomena (Transport), in Solids: Electrons and Phonons—the Theory of (Dr. J. M. Ziman), review by Prof. H. Jones, 821
 D-Phenylalanine, D-Allothreonine and other D-Amino-Acids in Peptido-Lipids of Bacterial Origin: Occurrence of (Dr. Miyoshi Ikawa, Dr. Esmond E. Snell and Dr. Edgar Lederer), 558
 Phenylketonuria in Infant Monkeys (Prof. Harry A. Waisman, Hwa L. Wang, Gail Palmer and Prof. Harry F. Harlow), 1124
 Phenylpropanoid Compounds in *Pyrus communis*: Biosynthesis of Arbutin from some (Prof. Sara K. Girdale and Prof. G. H. N. Towers), 1130
 Phillips, Glanfirid, and Davies, Clive: Science by the Upper Form (*Craspedocusta sowerbii*—Fresh Water Medusa of Microhydra), 455
 Phillips, John H., and Yardley, Benjamin J.: Detection in Invertebrates of Inducible, Reactive Materials resembling Antibody, 728
 Philosophical Society (American): Transactions, New Series, Vol. 50, Part 1, Contemporary Japan—the Individual and the Group (Dr. Yoshiharu Scott Matsumoto), 111
 Transactions, New Series, Vol. 50, Part 6, The Paleocene Pantodonta (Dr. E. L. Simons), 200
 Appointment of Dr. George W. Corner as executive officer, 784
 Philosophy of Science (Dr. B. C. Brookes), 457
 History and, review by Dorothea Waley Singer, 439
 The Structure of Scientific Thought, an Introduction to (Dr. Edward H. Madden), review by F. I. G. Rawlins, 831
 Whitehead's (Dr. Robert M. Palter), review by F. I. G. Rawlins, 829
 Philosophy of Science, British Society for the: Fifth Annual Conference, 457
 Philpott, D. E. (Bettelheim, Prof. F. A., and): Crystallinity of Calcium Chondroitin Sulphate, 654
Phoma terrestris Hansen: The Pigment of (Dr. D. E. Wright and Dr. K. Schofield), 233
 Phonons: Electrons and—the Theory of Transport Phenomena in Solids (Dr. J. M. Ziman), review by Prof. H. Jones, 821
 Phosphatase Action (Tryptic and), on certain Synthetic Phosphorylated Peptides (Dr. D. Theodoropoulos, Prof. J. Gazopoulos and I. Souclieris), 489
 Phosphatase Activity (Aldolase and), in the Cactus Plant: Diurnal Variation in (G. G. Sanwal and Prof. P. S. Krishnan), 664
 Phosphatase (Acid) Activity in Cells of Prostatic Tumours: Determination of (P. L. Esposti, B. Estborn and J. Zajicek), 663
 Phosphate Triester Groups: Phospholipids containing (Dr. F. D. Collins), 297
 Phosphate and Salt Uptake by Baker's Yeast (J. E. Leggett and Dr. S. B. Hendricks), 862
 Phosphate and Soil-Water Systems: Aluminium Ions in Aluminium Hydroxide, (M. Raupach), 1049
 Phosphatide (Human Platelet): The Half-life of (Dr. Charles M. Grossman, Alan M. MacEwan and James Dille), 950
 Phosphatide (Inositol), in Peas (Dr. L. M. Lewin and Prof. A. C. Wagenknecht), 146
 Phosphide (Gallium) Point-Contact Diodes: Radiative Recombination in (H. C. Gorton, J. M. Swartz and C. S. Peet), 303
 Phosphokinase (Creatine): A Theory of the Mechanism of Action of (Dr. B. R. Rabin and D. C. Watts), 1163
 Phospholipids containing Phosphate Triester Groups (Dr. F. D. Collins), 297
 Phosphoric Acid: Gas Chromatography of Unesterified Fatty Acids using Polyester Columns treated with (Dr. L. D. Metcalfe), 142
 Phosphorus: Transport of, by Fungal Mycelium (Dr. R. L. Lucas), 763
 Phosphorus-32: Uptake of, by the Roots of *Lolium perenne* (Arthur Troughton), 593
 Phosphorus-32 (Incorporated): Prevention of the Lethal Effect of the Decay of, by Growth at 45° (Dr. Ruth F. Hill), 412
 Phosphorus (Soil): Effect of Water-stress on the Absorption of, by Wheat Plants (R. G. Fawcett and Dr. J. P. Quirk), 687
 Phosphorus Pentachloride: Fine Structure of the Nuclear Magnetic Resonance Spectra of Solids—Chemical Shift Structure of the Spectrum of (Prof. E. R. Andrew, A. Bradbury, Dr. R. G. Eades and G. J. Jenks), 1096
 N-Phosphoryl-D- and L-Lombricine: Synthesis of (Iva M. Beatty, Prof. A. H. Ennor and Dr. D. I. Magrath), 1026
 Phosphorylated Peptides: Tryptic and Phosphatase Action on certain Synthetic (Dr. D. Theodoropoulos, Prof. J. Gazopoulos and I. Souclieris), 489
 Phosphorylation as a Factor in promoting the Crabtree Effect in the Amytal Ascites Sarcoma of White Mice (S. Braun, M. Erdélyi and A. Udvardy), 857

- Phosphorylation (Oxidative), in Cold-exposed Rats : Thyroid Function and (Dr. Sylva Panagos Lianides and Dr. Robert E. Beyer), 1196
- Photo-Assimilation of Acetate by Green Organisms (Prof. E. G. Pringsheim and Dr. W. Wiessner), 919
- Photochemical Oxidation of Sulphur Dioxide : Detection of, by Condensation Nuclei Techniques (S. B. Dunham), 51
- Photogrammetry—Basic Principles and General Survey (Prof. Bertil Hallert), review by Dr. D. H. Maling, 828
- Photographic Method : The Study of Elementary Particles by the (Prof. C. F. Powell, P. H. Fowler and Dr. D. H. Parkins), review by Prof. G. D. Rochester, 175
- Photographic Studies of Fish Populations (R. E. Craig and R. Priestley), 333
- Photographing Superficial Microbial Colonies : An Improved Method for (Prof. G. Nogrady), 602
- Photographs (Soviet) : Moon Maps, with a Chart showing the Other Side of the Moon based upon (H. P. Wilkins), review by Simone Daro Gosner, 88
- Photography Works : How (Dr. H. J. Walls), review by R. B. Collins, 841
- Photography (Ultra-Violet), of Fluorescent Spots on Chromatograms of Biological Extracts (Prof. Denis Abelson), 850
- Photoionization Detector for Gases and Vapours (Dr. J. E. Lovelock), 401
- Photolysis (Flash), of Carbon Disulphide, Formation of Vibrationally Excited Carbon Monosulphide and Sulphur by the (Dr. A. B. Callear and Prof. R. G. W. Norrish), 53
- Photons (Soft Ultra-violet), in Self-quenching Geiger-Müller Counters (Prof. Rafi Mohammed Chaudhri and Rahmat Ullah), 131
- Photoperiod (Decreasing), inhibiting Metamorphosis in an Insect (G. M. Blake), 168
- Photophosphorylation : Re-assessment of the Stoichiometry of (Dr. N. E. Good), 661
- Photoproducts (Low-Temperature) : Regeneration of Visual Pigments from their (Dr. Ruth Hubbard and Dr. Allen Kropf), 68 ; (Dr. C. D. B. Bridges), 69
- Photosynthetic Mutants in Unicellular Algae : A Screening Technique for (Prof. R. P. Levine), 339
- Phycobilin Formation : Studies on, with Mutants of *Cyanidium caldarium* (Kenneth E. Nichols and Lawrence Bogorad), 870
- Phycocyanin : A Possible Function of, in Intertidal Red Algae (A. D. Boney and E. D. S. Corner), 1042
- Physical Anthropology : An Introduction to (Prof. M. F. Ashley Montagu), third edition, review by Dr. J. S. Weiner, 807
- Physical Chemistry : Annual Review of (edited by H. Eyring, in association with C. J. Christensen and H. S. Johnston), Vol. 10, review by Prof. J. R. Partington, 264
- Fundamentals of (Prof. H. D. Crockford and Prof. Samuel B. Knight), review, 837
- Physical Chemistry of Aerosols (Faraday Society Discussion on), 630
- Physical Metallurgy (Extractive and), of Plutonium and its Alloys (edited by W. D. Wilkinson), (Based on a Symposium held in San Francisco, 1959), review by Prof. C. R. Tottle, 826
- Physical Parameters of the Atmospheric Escape Layer (Dr. John J. Gilvray), 804
- Physical Problems in Travelling at Supersonic Speed : Some (Dr. F. P. Bowden), 454
- Physical Society : Duddell Medal presented to Prof. R. V. Jones, 369
- Duddell Medal Address, Some Developments of the Optical Lever (Prof. R. V. Jones), 369
- Physical Society (Acoustics Group) : Symposium on Sound Propagation in the Atmosphere, 992
- Physical Society (Institute of Physics and the) : Conference on Diamond Physics, 368
- Annual Exhibition of Scientific Instruments and Apparatus, 454, 1153
- Annual Reports for 1959, 462
- Conference on Physics of Polymers, 539
- Duddell Medal awarded to Dr. J. B. Adams, 710
- Charles Vernon Boys Prize awarded to Prof. A. W. Merrison, 810
- Charles Chree Medal and Prize awarded to Dr. S. E. Forbush, 710
- Appointment of Dr. D. Shoenberg as Guthrie Lecturer for 1961, 710
- Appointment of Dr. H. H. Hopkins as Thomas Young Orator for 1961, 710
- Handbook of Scientific Instruments and Apparatus, 1153
- Physical Society (American), and others (sponsored by the) : The Exploration of Space—a Symposium on Space Physics, 1959 (edited by Robert Jastrow), review by D. G. King-Hele, 1058
- Physicists (Reactor) : Training Nuclear Engineers and, 897
- Physico-Chemical Constants of Binary Systems in Concentrated Solutions (Prof. Jean Timmermans), Vol. 3, Systems with Metallic Compounds, review by Dr. E. F. G. Herington, 819
- Physico-Chemical Properties of Purified Cytochrome *a* (Shigeki Takemori, Ichiro Sekuzu and Kazuo Okunuku), 593
- Physics in Hong Kong, 781
- Physics : Analytical and Canonical Formalism in (Prof. André Mercier), review by Prof. T. A. A. Broadbent, 840
- A Degree (Dr. C. J. Smith), Part 5, Electricity and Magnetism, second edition, review by Prof. H. Lipson, 1061
- Diamond (Institute of Physics and the Physical Society Conference on), 368
- High-Energy—Tenth Rochester Conference (E. M. Hafner), 778
- Modern (Prof. H. A. Wilson), fourth edition, review by Prof. H. Lipson, 839
- Nobel Prize for, awarded to Prof. Donald A. Glaser, 624
- Plasma (Dr. J. G. Linhart), review by Prof. D. Gabor, 822
- University (Prof. F. C. Champion), revised edition, review by Prof. H. Lipson, 840
- Physics, Institute of, and the Physical Society : Conference on Diamond Physics, 368
- Annual Exhibition of Scientific Instruments and Apparatus, 454, 1153
- Annual Reports for 1959, 462
- Conference on Physics of Polymers, 539
- Duddell Medal awarded to Dr. J. B. Adams, 710
- Charles Vernon Boys Prize awarded to Prof. A. W. Merrison, 710
- Charles Chree Medal and Prize awarded to Dr. S. E. Forbush, 710
- Appointment of Dr. D. Shoenberg as Guthrie Lecturer for 1961, 710
- Appointment of Dr. H. H. Hopkins as Thomas Young Orator for 1961, 710
- Handbook of Scientific Instruments and Apparatus, 1153
- Physics of Electricity and Magnetism (Prof. William Taussig Scott), review by G. R. Noakes, 1061
- Physics of the Ocean (Dr. G. E. R. Deacon), 454
- Physics of Polymers (Institute of Physics and the Physical Society Conference on), 539
- Physics of Semiconductors (International Union of Pure and Applied Physics International Conference on), 632
- Physics (Cloud), at the Imperial College of Science and Technology, London, 781
- Physics (Experimental) : Methods of (edited by Immanuel Estermann), Vol. 1, Classical Methods, review by G. R. Noakes, 839
- Physics (Nuclear) : Progress in (edited by Prof. O. R. Frisch), Vol. 7, review by Dr. E. Bratscher, 697
- Physics (Plasma) : Basic Data of (Prof. Sanborn C. Brown), review by Prof. D. Gabor, 822
- Physics (Pure and Applied), International Union of : International Conference on the Physics of Semiconductors, 632
- Physics (Pure and Applied), International Union of, and others : International Conference on Physics Education, 107
- Physics (Solid State), at Harwell, 537
- Physics (Theoretical Atomic), in Norway, 986
- Physics (Vacuum) : Standard Unit of Pressure in (Dr. N. A. Florescu), 303 ; (P. H. Biggs), 1017
- Physics Education : International Conference on (J. M. A. Lenihan), 107
- Physics and Engineering : Mathematics in (J. Irving and N. Mullineux), review by Prof. L. S. Goddard, 89
- Physikalischen Chemie : Lehrbuch der (Prof. John Eggert), achte Auflage, review by Prof. J. R. Partington, 973
- Physikalischer Gesellschaften (Verband Deutscher) : Fifth International Conference on Ionization Phenomena in Gases, 1075
- Physiological Carcinology, review by Dr. J. Green, 810
- Physiological Sciences, International Union of (Section of Pharmacology) : International Pharmacological Meeting on the Mode of Action of Drugs, 784
- Physiological Society : Monograph No. 6, Physiology of the Retina and the Visual Pathway (Dr. G. S. Brindley), review by Prof. George Wald, 261
- Physiology at Birmingham, 103
- Physiology at the Royal Free Hospital School of Medicine, London, 189
- Physiology : Annual Review of (edited by Victor E. Hall, in association with Prof. Frederick A. Fuhrman and Arthur C. Giese), Vol. 22, review by Dr. J. H. Gaddum, 90
- Physiology of the Banana Plant (Prof. F. C. Steward and colleagues), 27
- Physiology of Crustacea (edited by Talbot H. Waterman), Vol. 1, Metabolism and Growth, review by Dr. J. Green, 810
- Physiology of the Retina and the Visual Pathway (Dr. G. S. Brindley), review by Prof. George Wald, 261
- Physiology (Plant) : Didactic, review by Prof. W. O. James, 811
- Phytogeography of the Australian Region (Dr. Nancy T. Burbidge), 544
- Phytoplankton : Ophiuroids feeding on (H. M. Roushdy and Vagn. Kr. Hansen), 517
- Pichamuthu, Prof. C. S. : Charnockite in the Making, 135
- Picker (James) Foundation : Radiological Research Awards for 1961-62, 105
- Pickvance, T. J., and Chard, J. S. R. : Feral Muntjac Deer (*Muntiacus spp*) in the West Midlands, 463
- Picrotoxin : Effects of γ -Aminobutyric Acid and, on Spontaneous Activity in the Central Nervous System of the Crayfish (Prof. Joseph K. Hichar), 1117
- Pierce, Dr. Alan E. : β -Lactoglobulins in the Urine of the New-born Suckled Calf, 940
- Piez, Dr. Karl A., and others : Proteolysis in Stored Serum and its Possible Significance in Cell Culture, 59
- Piggott, W. R. : Promoted to Senior Principal Scientific Officer in the Scientific Civil Service, 281 ; work of, 281
- Pigment of *Phoma terrestris* Hansen (Dr. D. E. Wright and Dr. K. Schofield), 233
- Pigment (Visual), from a Pure-Cone Retina (Dr. H. J. A. Dartnall), 475
- Pigments of a Fossil Echinoderm (Dr. Max Blumer), 1100
- Pigments (Chloroplast), of Wheat Seedlings : Influence of Amino Triazole on the (Prof. Frederick T. Wolf), 164
- Pigments (Plankton), in Australian Waters : The Concentration of (Dr. G. F. Humphrey), 199
- Pigments (Visual) : Regeneration of, from their Low-Temperature Photoproducts (Dr. Ruth Hubbard and Dr. Allen Kropf), 68 ; (Dr. C. D. B. Bridges), 69
- Piggott, Sir Berkeley, and others : The New Forest, review by Dr. L. E. Tavenner, 829
- Pigs : Role of Cerebral Fat in the Production of Nutritional Disease in (B. Thafvelin), 1169
- Toxicity of a Single Subcutaneous Dose of Sodium Selenite in (Kerstin Orstadius), 1117
- Pilkat, B., and others : Effects of X-irradiation on Papillary Muscle of the Cat, 413
- Pineapple : Serotonin in (D. W. Bruce), 147
- Pile-Irradiated Graphite : Small-Angle X-Ray Scattering by (W. T. Eeles), 287
- Pinchin, F. J. : Reaction of Aromatic Compounds with a Chlorinated Coal and Aluminium Chloride, 848
- β -Pinene : Radiation-induced Ionic Reactions—the Retardation of the Homopolymerizations of α -Methyl Styrene and, by Water (T. H. Bates, J. V. F. Best and T. Ffranco Williams), 469
- Pinner, S. H., and Davison, W. H. T. : High Voltage Accelerators (Patents involving Radiation), 785
- Pioneer Contributions to Textile Technology : Chemistry in Scotland and its (Dr. A. Clow), 988
- Piper nigrum L. (Black Pepper), in Sarawak : Toxicity of Aluminium to (P. W. F. de Waard and C. D. Sutton), 1129
- Pirenne, Dr. M. H. : At the fifth Annual Conference of the British Society for the Philosophy of Science (Experiments to Determine the Threshold Intensity of Light visible to the Human Eye), 458
- Pirie, N. W. : Biology of Space Travel (Synthesis of Re-cycling of Oxygen, Food and Water on Longer Space Flights), 1079
- Psidium sativum* L. : Increase in Level of Chlorophyll in (Effect of Polyvinyl Alcohol on Chlorophyll and Haem in *Chlorella* and *Tendipes*), (Dr. Leopold Rejciak, Dr. Henryk Fr. Nowak and Bazyl Czeczuga), 120
- Pitt, Frances : Sea Birds, review, 1139

- Pitt, Dr. G. A. J. (Thompson, J. N., and) . Vitamin A Acid and Hypervitaminosis A, 672
- Pituitary (Human Anterior) : Importance of Insulin and of the Adrenal Cortex in determining the Toxicity in Baboons (*Popio ursinus*) to (Prof. Joseph Gillman, Christine Gilbert and Edward Epstein), 861
- Pituitary Glands (Sheep Anterior) : Effect of Season on the Follicle Stimulating Hormone and Luteinizing Hormone Potency of (J. S. M. Hutchinson and Dr. Hamish Robertson), 585
- Pozani, Dr. Rafael : Organization of Scientific Research in Latin America, 1157
- Placenta : *In vitro* Uptake of Iodine-131 by Salivary Glands, Stomach and (Prof. M. Maqsood and E. P. Reineke), 952
- Plane Waves : Aberration of (Dr. E. F. Fahy), 396
- Planet Saturn : Radio Detection of the (J. J. Cook, L. G. Cross, M. E. Blair and C. B. Arnold), 393
- Plankton of the Gulf of Guinea : Occurrence of *Calanoides carinatus* (Kroyer) in the (Dr. V. Bainbridge), 932
- Plankton Pigments in Australian Waters : The Concentration of (Dr. G. F. Humphrey), 199
- Plant *Pueraria mirifica* : Miroestrol, an Estrogen from the (Dr. James C. Cain), 774
- Plant (Banana) : Physiology of the (Prof. F. C. Steward and colleagues), 27
- Plant (Cactus) : Diurnal Variation in Aldolase and Phosphatase Activity in the (G. G. Sanwal and Prof. P. S. Krishnan), 664
- Plant Cells : New Evidence for a Relationship between Ion Absorption and Protein Turnover in (Dr. J. F. Sutcliffe), 294
- Occurrence and Distribution of Cytochrome $a + a_3$ in (Prof. W. O. James and Anne M. Richens), 423
- Plant Design (Nuclear Power) : Evolution of (Sir Christopher Hinton), *errata*, 24
- Plant Geography, review by Dr. W. B. Turrill, 882
- Plant Geography and some related Sciences : Introduction to (Prof. Nicholas Polunin), review by Dr. W. B. Turrill, 882
- Plant Growth : Control of, review by Dr. D. J. Watson, 1060
- Plant Growth Regulating Activity of Auxin-Type Chemicals : Morphological Reactions of Germinating Seeds as Criteria for the (J. Sudi, Gy. Josepovits and Gy. Matolcsy), 244
- Plant Growth Regulator Acids : Evidence of a Specific Action on the Central Nervous System by the Esters of some (Dr. J. Thuillier, Germaine Thuillier and P. Rumpf), 152
- Plant Growth Substances : Changes in Sex in the Hop caused by (E. W. Weston), 81
- Plant Gums and Mucilages and some related Polysaccharides : The Chemistry of (Prof. F. Smith and Prof. R. Montgomery), review by Prof. M. Stacey, 820
- Plant Materials : Quantitative Isolation of Alkaloids from (Dr. Lee Kuntz), 65
- Plant Mitochondria : Effects of α -Lipoic Acid on the Respiratory Chain of (J. T. Wiskich and Prof. R. K. Morton), 658
- Plant Pathology (edited by J. G. Horsfall and A. E. Diamond), Vol. 2, The Pathogen, review by W. C. Moore, 835 ; Vol. 3, The Diseased Population, Epidemics and Control, review by W. C. Moore, 884
- Plant Phenolics Group : Meeting on the Stereochemistry of Natural Phenolic Compounds, 367
- Plant Physiology : Didactic, review by Prof. W. O. James, 811
- Plant Population and Crop Yield (Dr. J. K. A. Bleasdale and J. A. Nelder), 342
- Plant Resources of the Middle East and South Asia for the Pharmaceutical Industry and Rauwolfia (Government of Pakistan, Unesco Middle East Science Co-operation Office and the Unesco South Asia Science Co-operation Office Symposium on), 539
- Plant and Bacterial Viruses (edited by F. M. Burnet and W. M. Stanley), (The Viruses—Biochemical, Biological and Biophysical Properties, Vol. 2), review by F. C. Bawden, 882
- Plants : Growing Points in, review by Dr. F. A. L. Clowes, 1141
- Juvenile Hormone Activity in Micro-organisms and (Prof. Howard A. Schneiderman, Dr. Lawrence I. Gilbert and Dr. Marvin J. Weinstein), 1041
- Plants (*Atropa belladonna*) : Rate of Formation of Atropine in (J. R. Catch and E. A. Evans), 758
- Plants (Flowering) : Gibberellin and Sex Differentiation of (Dr. R. Herich), 599
- Taxonomy of (C. L. Porter), review by J. P. M. Brennan, 835
- Plants (Higher) : Hydroxyproline in Primary Cell Walls of (Derek T. A. Lamport and Dr. D. H. Northcote), 665
- Utilization of Nitric Oxide by Micro-organisms and (C. A. Fewson and Dr. D. J. D. Nicholas), 794
- Plants (Medicinal), of the Arid Zones (Arid Zone Research Series), (Unesco), 23
- Plants (Pasture) : Interspecific Differences in Strontium Uptake by, as a Function of Root Cation-Exchange Capacity (M. C. H. Mount), 513
- Plants (Wheat) : Effect of Water-stress on the Absorption of Soil Phosphorus by (R. G. Fawcett and Dr. J. P. Quirk), 687
- Plants and Decay (Filmstrips showing the Origin, Composition and Use of Soil, 2), (Marian Ray), 783
- Plaque Formation by an Orphan Virus of Fowls (I. A. Macpherson), 1213
- Plaque Technique for the Primary Isolation of Arthropod-borne Viruses (Dr. J. S. Porterfield, Dr. M. C. Williams and Dr. J. P. Woodall), 252
- Plaskett, Dr. L. G. : Appointed lecturer in biochemistry at the University of Edinburgh, 539
- Plasma : Forces on a Charged Particle of a , in a Cavity Resonator (J. W. Gallop, T. L. Dutt and H. Gibson), 397
- Nature of the Leucocytosis-inducing Factor in (Prof. Tokuro Fukuda, Hiroshi Oide and Atsushi Miyasaka), 860
- Proteins Induced in, by Estrogens (Dr. O. A. Schjælde and Dr. M. R. Uriet), 291, (Prof. R. H. Common), 293
- The 'Serial Thrombin Time' Method for measuring Fibrinolytic Activity in (Dr. G. L. C. Ingram and Myrtle O. Matchett), 674
- Plasma of Human Arterial Blood : Composition of the Free Fatty Acid Fraction in the (C. Chlouverskis and Dr. Peter Harris), 1111
- Plasma (Hot) : Gas-insulation of a (Prof. Hannes Alfvén and Erik Smårs), 801
- Plasma (Human), collected during Labour : Spontaneous Plasma Kinin Formation in (Dr. Desirée A. J. Armstrong and Dr. J. W. Stewart), 1193
- Plasma Kinin Formation (Spontaneous), in Human Plasma collected during Labour (Dr. Desirée A. J. Armstrong and Dr. J. W. Stewart), 1193
- Plasma Physics (Dr. J. G. Linhart), review by Prof. D. Gabor, 822
- Basic Data of (Prof. Sanborn C. Brown), review by Prof. D. Gabor, 822
- Plasma Proteins (edited by Frank W. Putnam), Vol. 1, Isolation, Characterization and Function ; Vol. 2, Biosynthesis, Metabolism, Alterations in Disease, review by Dr. R. Conden, 816
- Plasma Proteins in Mammals : Turnovers of Erythrocytes and (Dr. A. C. Allison), 37
- Plasma Proteins of Man : Early Incorporation of Sulphur-35 Sodium Sulphate in (Dr. Bernard A. Sachs, Edward Siegel and Joseph V. Marino), 1125
- Plasminogen Contaminant in Thrombin : Selective Inactivation of the (Dr. Gabor Markus and Dr. Clara M. Ambrus), 582
- Plasminogen Preparations (Human) : Identification of Ultracentrifugal Components in (Prof. Sidney Shulman), 161
- Plasmodium Formation by the True Slime Mould, *Didymium nigripes* : Effect of Chelating Agents on (Prof. Norman S. Kerr), 1206
- Plasticity of Wool (P. de Wae, Prof. J. B. Speakman and K. J. Whiteley), 69
- Plastics : Fellowships for Engineering Study and Fundamental Research in (Princeton University), 711
- New Developments in (Bradford Chemical Society, the Yorkshire Section of the Plastics Institute, the Department of Chemical Technology of the Bradford Institute of Technology, in conjunction with the Yorkshire Council for Further Education Symposium on), 699
- Plastics Institute : Christmas Lecture by Dr. H. A. Thomas (Plastics and Textiles), 1075
- Plastics Institute (Yorkshire Section), and others : Symposium on New Developments in Plastics, 899
- Plastics and Polymer Chemistry : Recent Developments in (Department of Chemical Technology of the Bradford Institute of Technology Course on), 24
- Plastics and Textiles (Dr. H. A. Thomas), 1075
- Plastics (Rubber and) Research Association of Great Britain : Adoption of Articles, 708
- Plate (A Gular), in *Albula vulpes* (L.), (Prof. Orvar Nybelin), 78
- Plate Assay for Elastase (Dr. Anthony J. Sbarra, Robert F. Giffilan and Wadi A. Bardawil), 322
- Plate Method for Studying the Breakdown of Synthetic and Natural Silicates by Soil Bacteria (Dr. D. M. Webley, Dr. R. B. Duff and W. A. Mitchell), 766
- Platelet Phosphatide (Human) : The Half-life of (Dr. Charles M. Grossman, Alan M. MacEwan and James Dilley), 950
- Platelets of Patients with Idiopathic Thrombocytopenic Purpura : Difference between γ -Globulins fixed on the, and of those suffering from Disseminated Lupus Erythematosus or a Panhaematocytopenia (Prof. J. Dausset, J. Colombani and M. Colin), 865
- Plato and Cicero : Religion in (John E. Rexine), review, 831
- Plaut, Prof. W. (Krause, Margarida, and) . An Effect of Tritiated Thymidine on the Incorporation of Thymidine into Chromosomal Deoxyribonucleic Acid, 511
- Plesch, Dr. P. H. : At the Tenth Canadian High Polymer Forum (Natural and Synthetic Macromolecules), 456
- Plowright, W., and others : Blue Wildebeest and the Aetiological Agent of Bovine Malignant Catarrhal Fever, 1167
- Plump, H. : Calorimetry (Low Temperature Thermometry at the National Bureau of Standards), 788
- Plutonium and its Alloys, review by Prof. C. R. Tottle, 826
- Extractive and Physical Metallurgy of (edited by W. D. Wilkinson), (Based on a Symposium held in San Francisco, 1959), review by Prof. C. R. Tottle, 826
- Pocock, Dr. M. A. : The Water Net, *Hydrodictyon*, 545
- Podlaha, Jaroslav, and Ebert, Miroslav : Triphosphotchromic Acid, 657
- Podoba, Dr. J. (Stolc, V., and) : Effect of Fluoride on the Biogenesis of Thyroid Hormones, 855
- Podolsky, Dr. R. J. : Kinetics of Muscular Contraction—the Approach to the Steady State, 666
- Point-Contact Diodes (Gallium Phosphide) : Radiative Recombination in (H. C. Gorton, J. M. Swartz and C. S. Peet), 303
- Points (Growing), in Plants, review by Dr. F. A. L. Clowes, 1141
- Poison Sprays and Wild Life, 366
- Poisoning (Food), Food-borne Infection and Intoxication (Elliot B. Dewberry), fourth edition, review by Dr. F. H. Banfield, 836
- Poisoning (Mussel) : Histochemical Demonstration of the Mode of Action of the Alkaloid in (W. J. Pepler and E. Loubser), 860
- Poisons (Anticoagulant) : Case of Apparent Resistance of *Rattus norvegicus* Berkenhout to (C. Mary Boyle), 517
- Poisson Inputs (Ordered) : Time-Dependent Results for a Dam with (J. Gani), 341
- Polani, Dr. P. E. : Appointed to the Prince Philip chair of paediatric research at Guy's Hospital Medical School, London, 279
- Polar Latitudes : Propagation of Whistlers to (G. McK. Allcock), 732
- Polarity in Flax Buds : Experiments on (H. F. Gulline), 23
- Polarizations (Atomic), of Chloro-, Bromo- and Iodo-benzene (Dr. H. H. Huang and Dr. E. P. A. Sullivan), 1104
- Polarography (Oscillographic), of Highly Polymerized Deoxyribonucleic Acid (Emil Paleček), 656
- Policy in Perspective (British Association for Commercial and Industrial Education Annual Conference), 257
- Policy (Scientific), Advisory Council on : Thirteenth Annual Report (1959-60), 435
- Policy (Scientific), and Research Effort : British, 896
- Poliomyelitis : Virus Survival as a Seasonal Factor in Influenza and (J. H. Hemmes, Prof. K. C. Winkler and S. M. Kool), 430
- Poliiovirus : Concentration of, by an Aqueous Polymer Two-Phase System (E. C. J. Norrby and Dr. P. A. Albertsson), 1047
- Polish Publications : New, Nos. 1-5 (Aspol Foreign Trade, Advertising and Publishing Agency, Warsaw), 784

- Problem of Chromium in Water Supplies, 987
- Problems of Chemical Kinetics and Reactivity : Some, Vol. 1 (Academician N. N. Semenov), translated by Dr. J. E. S. Bradley, review by Prof. J. R. Partington, 699
- Problems of Progress in Industry : No. 8, Ergonomics of Automation, 986 ; No. 9, Automation and Skill (E. R. F. W. Crossman), 986 (Department of Scientific and Industrial Research)
- Problems of University Development : Some (Association of University Teachers), 789
- Problems (Critical), in the History of Science—Proceedings of the Institute for the History of Science at the University of Wisconsin, 1957 (edited by Marshall Clagett), *review* by Dorothea Waley Singer, 439
- Problems (Medico-sanitary) : National Health Institutes and Actual Research and (World Health Organization International Symposium on), 711
- Problems (Some Physical), in Travelling at Supersonic Speed (Dr. F. P. Bowden), 454
- Probstein, Ronald F. (Hayes, Wallace D., and) : Hypersonic Flow Theory, *review* by Dr. W. P. Jones, 822
- Procedure for Admission of Students (Association of Universities of the British Commonwealth), 716
- Process (Cholinergic), in Sympathetic Transmission : New Evidence for a (Dr. M. J. Rand and Dr. V. Chang), 858
- Processes (Denudational), on Slopes : Soil Movement by (Dr. Anthony Young), 120
- Processing of Data from Geiger-Muller Counters : Automatic Equipment for the Collection and (Dr. Richard Scott), 161
- Processing of Uranium : Production and, *review* by D. E. R. Hughes, 348
- Processing (Data), and Automatic Control : Instrumentation, *review* by P. H. Hammond, 827
- Procter, Brian T. : Awarded the Vickers-Armstrongs Scholarship in Naval Architecture (1960) by the Royal Institution of Naval Architects, 106
- Production of Acid Mucopolysaccharides by Fibroblasts in Cell Cultures (Dr. C. C. Morris and Dr. G. C. Godman), 407
- Production of D-Araboascorbic Acid by *Penicillium* (Prof. T. Takahashi, M. Mitsumoto and H. Kayamori), 411
- Production of Free Water in the Mammalian Foetus (M. W. Stanier), 237
- Production of Glucose during Hepatic Glycogenolysis : An Effect of insulin on (A. Dunn, R. Steele, N. Altzuler, Prof. R. C. de Bodo, J. S. Bishop and D. T. Armstrong), 236
- Production of Nutritional Disease in Pigs : Role of Cereal Fat in the (B. Threlwell), 1169
- Production of Vitamin B₁₂ by Trypanosomid Flagellates : Influence of Pteridines on the (Helene A. Nathan, Herman Baker and Oscar Frank), 35
- Production (Crop), and Environment (Dr. R. O. Whyte), new edition, *review* by Dr. D. J. Watson, 1060
- Production (Elective), of Thymine-less Mutants (Toshihiko Okada, Keiko Yanagisawa and Prof. Francis J. Ryan), 340
- Production Technology : Uranium (edited by C. D. Harrington and A. E. Ruehle), *review* by D. E. R. Hughes, 348
- Production and Processing of Uranium, *review* by D. E. R. Hughes, 348
- Productivity of the Sea and Fresh Water (British Association for the Advancement of Science, Section D (Zoology), Discussion on), 91
- Products : Natural, *review* by Dr. T. G. Halsall, 440
- Products (Recombinant), of Canine and Human Haemoglobins : Identification of the (Elizabeth A. Robinson and Dr. Harvey A. Itano), 798
- Profile (Soil) Development : Glaciation in Wales as related to (Welsh Soils Discussion Group Session on), 367
- Profiles : Soil (Filmstrips showing the Origin, Composition and Use of Soil, 3), (Marian Ray), 783
- Profits : Early Thoughts on Progress and, *review* by Prof. S. G. Checkland, 1060
- Profits (Progress and), in British Economic Thought, 1650-1850 (Dr. G. S. L. Tucker), *review* by Prof. S. G. Checkland, 1060
- Programmers (Computer) : Selection and Training of (British Association for the Advancement of Science, Sub-section A* (Mathematics), Discussion on), 629
- Programming : Studies in Linear and Non-Linear (Prof. Kenneth J. Arrow, Prof. L. Hurwicz and Hirofumi Uzawa), *review* by Prof. L. S. Goddard, 6
- Programming and Economics : Mathematical Methods and Theory in Games, (Samuel Karlin), Vol. 1, Matrix Games, Programming and Mathematical Economics ; Vol. 2, The Theory of Infinite Games, *review* by Prof. L. S. Goddard, 825
- Programming and Mathematical Economics : Matrix Games, (Samuel Karlin), (Mathematical Methods and Theory in Games, Programming and Economics, Vol. 1), *review* by Prof. L. S. Goddard, 825
- Progress in Aeronomy (Dr. T. R. Kaiser), 712
- Progress of Applied Chemistry : Reports on the, Vol. 42, 1957 (Society of Chemical Industry), *review*, 836
- Progress in Automation (edited by Dr. A. D. Booth), Vol. 1, *review* by P. H. Hammond, 827
- Progress in Calorimetry, 787
- Progress of Cancer Research (D. G. Arnett, Dr. I. Hieger and A. Levene), 891
- Progress in Evolutionary Biology : A Century of, *review* by Dr. W. H. Thorpe, 525
- Progress in the Flora of Canada, *review* by Gordon P. DeWolf, jun., 349
- Progress in Industry : Problems of, No. 8, Ergonomics of Automation, 986, No. 9, Automation and Skill (E. R. F. W. Crossman), 986 (Department of Scientific and Industrial Research)
- Progress in Nuclear Physics (edited by Prof. O. R. Frisch), Vol. 7, *review* by Dr. E. Bratscher, 697
- Progress in the Study of Vision, *review* by Prof. George Wald, 261
- Progress and Profits : Early Thoughts on, *review* by Prof. S. G. Checkland, 1060
- Progress and Profits in British Economic Thought, 1650-1850 (Dr. G. S. L. Tucker), *review* by Prof. S. G. Checkland, 1060

- Research (Weather): Radar in, review by J. R. Probert-Jones, 526
- Research Association of British Paint, Colour and Varnish Manufacturers: Medal presented to Dr. L. A. Jordan, 628
- Research Associations (Industrial), in the Government Scheme: Research for Industry 1959—a Report on Work done by (Department of Scientific and Industrial Research), 195
- Research Awards (Radiological), for 1961-62 (James Picker Foundation), 105
- Research Centre (Regional), of the British Caribbean at the Imperial College of Tropical Agriculture: Soil and Land-Use Surveys, Monographs 4-10, 109
- Research Effort: British Scientific Policy and, 896
- Research Group (High Polymer): Foundation of the, 986
- Research Station: The Post Office (A. C. Lynch), 905
- Research Station, Low Temperature (Cambridge): Appointment of Dr. S. M. Partridge as head of the Eggs and Poultry Department, 988
- Future of the, 988
- Research and Development: The Choice of Subjects for (Sir Harold Hartley), 1055
- Industrial, 1055
- Reviews of Data on, No. 22, Funds for Basic Research in the United States, 1959-60 (United States National Science Foundation), 104
- Reserpine: Effect of, on Heart Mitochondria (Dr. Arnold Schwarz and Dr. Kwang Soo Lee), 948

- Reserpine Analogues** (Dr. T. Kralt, H. D. Moed, V. Claassen, Th. W. J. Hendriksen, A. Lindner, H. Selzer, F. Brucke, G. Hertzting and G. Gogolak), 1108
- Reserpine Depression** Accelerated Recovery from, by Monoamine Oxidase Inhibitors (Larry Stein and Oakley S. Ray), 1199
- Residue (Tryptophan)**, in the Reaction of Diisopropylphosphorofluoridate with α -Chymotrypsin. Evidence for the Involvement of a (John F. Wootton and Prof. George P. Hess), 726
- Residues (Guanylic Acid)**, in Tobacco Mosaic Virus Nucleic Acid Distribution of (Dr. K. K. Reddi), 60
- Resin (Ion-exchange)**. Preparation of Silver Iodide Sol by (P. Van der Wee), 655
- Resin Particles (Small) (1-5 μ Diameter)**: Uptake of, by the Alimentary Canal of the Calf (Dr. J. M. Payne, B. F. Sansom, R. J. Garner, A. R. Thomson and B. J. Miles), 586
- Resin-loaded Papers (Sulphonated Polystyrene)**: Separation of Amino-acid Mixtures on (C. S. Knight), 739
- Resistance of Oat Varieties to Races of Oat Stem Rust** Nature of the (Dr. Vernon D. Burrows), 957
- Resistance (Apparent)**, of *Rattus norvegicus* Berkenhout to Anticoagulant Poisons Case of (C. Mary Boyle), 517
- Resistant Strains of Micro-organisms**, 985
- Resistivity of Indium Antimonide**: Pressure Dependence of, to 70,000 Atmospheres (H. A. Gebbie, P. L. Smith, I. G. Austin and J. H. Kind), 1095
- Resistivity (Electrical)**, of Nickel Ferrite (Dr. H. Lord and Dr. R. Parker), 929
- Resonance (Electron Spin) Signal Strength from Guinea Pig Adrenals**: Correlation of Biological Activity and the (Frank K. Truby and Dr. Joseph W. Goldzieher), 1088
- Resonance (Electron-Spin) Splitting Constants of several Well-known Free Radicals**: Re-assessment of the (Dr. J. E. Bennett), 485
- Resonance (Magnetic)**, of Protons in Glasses (D. Elwell, D. Kumar and Dr. D. Williams), 1103
- Resonance (Proton Magnetic)**, of the Water Phase of Gelatin Gels (Erik Odeblad), 579
- Resonance Spectra (Nuclear Magnetic)**, of Solids. Fine Structure of the—Chemical Shift Structure of the Spectrum of Phosphorus Pentachloride (Prof. E. R. Andrew, A. Bradbury, Dr. R. G. Eades and G. J. Jenks), 1096
- Resonance Studies (Electron Paramagnetic)**, of Stable Free Radicals in Lignins and Humic Acids (Dr. R. W. Rex), 1185
- Resonances (Cavity)**: Observations of Earth-Ionosphere (M. Balser and C. A. Wagner), 638
- Resonant Scattering of the 14-keV, Iron-57 γ -Ray, and its Interference with Rayleigh Scattering** (Dr. P. J. Black and Prof. P. B. Moon), 481
- Resonator (Cavity)**: Forces on Charged Particles of a Plasma in a (J. W. Gallop, T. L. Dutt and H. Gibson), 397
- Resources**: Science and (edited by Henry Jarrett), review by Sir Harry Melville, 807
- Resources (Natural)**, in Scotland (Scottish Council's Committee on Natural Resources Symposium on), 106
- Resources (Plant)**, of the Middle East and South Asia for the Pharmaceutical Industry and Rauwolfia (Government of Pakistan, Unesco Middle East Science Co-operation Office and the Unesco South Asia Science Co-operation Office Symposium on), 539
- Respiration of Rous Sarcoma and of Choriocarcinoma Membrane**: Effect of Glucose Concentration on (Prof. Alvin S. Levine, Frances Stricker, Richard Uhl and James Ashmore), 229
- Respiration (Tissue)**, and Transamination in Cold Stress (Prof. D. P. Sadhu), 672
- Respiratory Chain of Plant Mitochondria**: Effects of α -Lipoic Acid on the (J. T. Wiskich and Prof. R. K. Morton), 658
- Response (Antibody)**: Specificity and Inheritance of—a Possible Steering Mechanism (Dr. B. Cnader), 619
- Response (Biochemical)**, to Injury—a Symposium organized by the Council for International Organizations of Medical Sciences (edited by H. B. Stoner, with the assistance of C. J. Threlfall), review by Dr. M. G. Macfarlane, 810
- Response (A Composite)**, of Skin Homografts in the Rat (John Anderson), 679
- Response (Hypoglycaemic)**, to Leucine in a Leucine-sensitive Man (Prof. W. J. H. Butterfield, M. J. Whiclow, P. H. Wright and L. I. Woolf), 70
- Responsibility (Personal)**: Popular Culture and (National Union of Teachers Conference on), 24
- Results (Spectro-Analytical)** Evaluation and Presentation of (A. B. Calder), 277
- Retardation of the Homopolymerizations of α -Methyl Styrene and β -Pinene by Water**: Radiation-induced Ionic Reactions—the (T. H. Bates, J. V. F. Best and T. Ffrancis Williams), 469
- Reticular Formation**: Disorganization—Organization and the (Rodabé P. Bharucha-Reid), 123
- Reticulocytes**: Separation of, by means of Multi-Layer Centrifugation (Prof. Eichi Kimura, Tatsuo Suzuki and Yoshihiro Kinoshita), 1201
- Retina (Pure-Cone)**: Visual Pigment from a (Dr. H. J. A. Dartnall), 475
- Retina and the Visual Pathway**: Physiology of the (Dr. G. S. Brindley), review by Prof. George Wald, 261
- Reversed Phase Paper Chromatography**: Separation of Sphingosine and Dihydrospingosine by (Karl-Anders Karlsson), 312
- Reverses the Antibacterial Activity of 1-Methyl-3-nitro-1-nitrosoguanidine**. A Factor in Agar which (Dr. Joseph Greenberg), 660
- Reversible Behaviour of the Ultra-violet Irradiated Deoxyribonucleic Acid and its Apurinic Acid** (Shih Yi Wang), 844
- Reviews of Data on Research and Development**, No. 22, Funds for Basic Research in the United States, 1959-60 (United States National Science Foundation), 104
- Revision Notes on Biology for 'O' Level of the G.C.E.** (G. T. Bolton), review, 973
- Rex, Dr. R. W.**: Electron Paramagnetic Resonance Studies of Stable Free Radicals in Lignins and Humic Acids, 1185
- Rexine, John E.**: Religion in Plato and Cicero, review, 831
- Rheology—Theory and Applications** (edited by Frederick R. Eirich), Vol. 3, review by Dr. G. W. Scott Blair, 819
- Theoretical (British Society of Rheology Meeting on)**, 627
- Rheology, British Society of**: Meeting on Theoretical Rheology, 627
- Rhizobium lupini**: Transformation of a Strain of (R. Balassa), 246
- Rhizosphere Bacteria**. Chitin Breakdown of (Keeskés Mihály), 251
- Rhodesia (Southern)**, National Museums of. Annual Report for 1959, 22
- Rhodnius prolixus**. Synthesis of Thiamine and Folic Acid by *Nocardia rhodni*, the Micro-symbiont of (Dr. J. S. Harington), 1027
- Rhythmic Contraction of Single Cultured Cardiac Muscle Cells**: Specificity of the Effects of Cardiac Glycosides on the (Prof. Albert Wollenberger and Willi Halle), 1114
- Ribbons, D. W., and others**: New Pathways in the Oxidative Metabolism of Aromatic Compounds by Micro-organisms, 560
- Ribes**: Amphiplasty in (E. Keep), 339
- Ribonuclease**: Function of, in Germinating Peas (Dr. G. R. Barker and Thelma Douglas), 943
- Ribonucleic Acid**: Base Composition of, from Rat Mammary Gland during Pregnancy and Late Lactation (Dr. D. Y. Wang, T. F. Slater and Dr. A. L. Greenbaum), 320
- Some Molecular Details of the Secondary Structure of** (Prof. Jacques R. Fresco, Bruce M. Alberts and Prof. Paul Doty), 98
- Ribonucleic Acid from Tobacco Mosaic Virus**. Influence of a Quaternary Ammonium Salt on the Infectivity of (Leon Hirth, Genaviève Lebourrier, Dr. Geneviève Aubel-Sadron, Gisèle Beck, Jean-Pierre Ebel and Paul Horn), 689
- Ribonucleic Acid (Soluble)**, of Rabbit Liver: Spermine Fractionation of (Action of Spermine on Soluble Ribonucleic Acid and some Polynucleotides), (Dr. G. L. Cantoni), 300
- Ribonucleic Acid (Soluble)**, and some Polynucleotides. Action of Spermine on—Spermine Fractionation of Soluble Ribonucleic Acid of Rabbit Liver (Dr. G. L. Cantoni), 300, Solubility of Complexes of Polynucleotides with Spermine (S. Lee Huang and Dr. G. Felsenfeld), 301
- Ribonucleic Acid (Viral)**, and Protein Composition: Correlation of (Prof. Martynas Yčas), 209
- Ribonucleotides (Acid-soluble)**, of Rat Mammary Gland Effects of Short-term Weaning on the (Dr. D. Y. Wang), 1109
- Rice, Prof. F. O., and Cosgrave, D. P.**: Some Experiments on Rice's Blue Material—Colours on Jupiter, 1023
- Rice's Blue Material**: Some Experiments on—Colours on Jupiter (Prof. F. O. Rice and D. P. Cosgrave), 1023
- Rich, Prof. Arnold R.**: Awarded a grant of 5,000 dollars by the Gardner Foundation, 367
- Richards, Prof. E. J.**: Bio-mechanics (Noise Annoyance and its Assessment), 533
- Richards, Dr. Merfyn**: Botanical Aspects of Allergy (Mould Spore Population of the Air), 183
- Richards, Prof. W.**: Influence of Climate on Life (Life in the Tropics), 1081
- Richardson, D. A., and others**: Radiation-induced Defects in Lead Silicate Glass, 1181
- Richens, Anne M. (James, Prof. W. O., and)**: Occurrence and Distribution of Cytochrome a - a_3 in Plant Cells, 423
- Richmond, Dr. A.**: Appointed to a Research Fellowship in chemistry in the University of Hull, 539
- Richter, B. G.**: Fluctuations in the Level of the Caspian Sea, 105
- Richterich, R., and Franz, H. E.**: Isolation of Glomerula from Rat Kidney, 498
- Ricketts, Dr. C. R., and others**: Labelling of Inulin with Radioactive Iodine, 675
- Rickettsiae**: Presence of Cell Walls like those of Bacteria in (Dr. A. C. Allison and Dr. H. R. Perkins), 796
- Riddell, R. W., and others**: Misinterpretation of an Agar-Gel Precipitation Pattern, 685
- Riden, Robert**: Science by the Upper Form (The Caves of South Wales), 455
- Riding (Bow-) of Ships under Way**: Porpoises and the (Andrew A. Fejer and Richard A. Backus), 700
- Riel, Gordon K., and others**: Spectrum of Radiation Background under Water, 266
- Rietsema, Jacob, and others**: Blakeslee—the Genus *Datura*, review by R. D. Meikle, 834
- Rigby, B. J., and Spikes, J. D.**: Hydrothermal Denaturation of Collagen, 420
- Hydroxyproline and the Shrinkage Temperature of Collagen**, 1120
- Right and Left Sides**: Senile Dementia and Cerebral Oxygen Uptake measured on the (Irwin Feinberg, Mark H. Lane and Niels A. Lassen), 962
- Rijken, A. H. G. C., and Banbury, C. A.**: Role of the Grain Coat in Wheat Grain Development, 546
- Rinfret, A. P. (Dowell, L. G., and)**: Low-Temperature Forms of Ice as studied by X-Ray Diffraction, 1144
- Ring, Dr. J.**: Rocket and Satellite Instrumentation (Ultra-violet Measurements from Satellites), 265
- Ringworm (Human)**: The Hedgehog as a Source of (Prof. Mary J. Marples and J. M. B. Smith), 867
- Rioja, Dr. Enrique**: Migration of Marine Organisms, 635
- Ritchie, Alexander**: A New Interpretation of *Jamoytus kerwoodi* White, 647
- Rittmann, Prof. A.**: Presidential Address to the meeting of the International Association of Volcanology in Helsinki (Geochemistry of Basalts and the Mechanism of their Eruption), 789
- Elected president for 1960-63 of the International Association of Volcanology**, 789
- Ritzen, M., and others**: Storage and Release of Catecholamines, and the Occurrence of a Specific Submicroscopic Granulation in Hearts of Cyclostomes, 324
- Rivat, L., and others**: Possible Origins of the Anti-Gm Sera, 1120
- River Bottoms**: Cover on (Dr. D. Scott), 76
- River (Matjes) Rock Shelter** (Dr. Louw), 987
- Roach, F. E.**: Recent Advances in Aeronomy (Variations in the 5577 and 6300 Å Airglow Emissions), 713
- Road to Man**: The (Herbert Wendt), translated by Helen Sabba, review by L. A. Harvey, 8
- Road Research Laboratory**: Test Track for the (Dr. T. Lonsdale), 894
- Roane, jun., Philip R. (Roizman, Prof. Bernard, and)**: Polyoma Virus in Syrian Hamsters—a Non-communicable Infection, 1134
- Robbins, Dr. R. C. (Cadle, Dr. R. D., and)**: Physical Chemistry of Aerosols (Importance of Aerosols in Catalysing Chemical Reactions in the Atmosphere), 631

- Sciences (Medical), Council for International Organizations of : Symposium on the Biochemical Response to Injury (edited by H. B. Stoner, with the assistance of C. J. Threlfall), review by Dr. M. G. Macfarlane, 810
- Sciences (Physiological), International Union of (Section of Pharmacology) : International Pharmacological Meeting on the Mode of Action of Drugs, 784
- Sciences et Techniques Nucléaires, Institut National des : Symposium de Métallurgie Spéciale (Saclay, 1957), review by Prof. C. R. Tottle, 179
- Scientific Civil Service : Promotions in the, 280
- Scientific Effort (British) : The Balance of, 435
- Scientific Film Association (International) : Fourteenth Annual Congress (Maurice Goldsmith), 371
- Election of Officers, 372
- Scientific Information : Collecting and Communicating (Northampton College of Advanced Technology, London, Courses on), 1153
- Proceedings of the International Conference on (Washington, D.C., 1958), review by C. A. Ronan, 973
- Scientific Instrument Industry : Careers in the (Scientific Instrument Manufacturers' Association), 1155
- Scientific Instrument Manufacturers' Association : Careers in the Scientific Instrument Industry, 1155
- Scientific Instruments and Apparatus (Institute of Physics and the Physical Society's Annual Exhibition of), 454, 1153 ; Handbook of, 1153
- Scientific Manpower (Joyce Alexander), review, 352
- Scientific Periodical Publications : Cost of (M. W. Perrin), 1052 ; (D. B. Baker), 1052
- Scientific Policy, Advisory Council on : Thirteenth Annual Report (1959-60), 435
- Scientific Policy and Research Effort : British, 896
- Scientific Programmes in the Antarctic : United States, 710
- Scientific Research in Latin America : Organization of (Unesco Science Co-operation Office for Latin America Discussion on), 1157
- Scientific Research (Applied), Central Netherlands Organization for : Report by the Fibre Research Institute on Mounting Boards, 191
- Scientific Societies in Britain : Tax Assessment for, 1072
- Scientific Thought : The Structure of—an Introduction to Philosophy of Science (Dr. Edward H. Madden), review by F. I. G. Rawlins, 831
- Scientific and Industrial Research, Council for : Appointment of Prof. B. Bleaney and Dr. James Cook as members, 193
- Scientific and Industrial Research, Department of : Research for Industry 1959—a Report on Work done by Industrial Research Associations in the Government Scheme, 195
- Promotion of Dr. L. Essen (National Physical Laboratory) to Deputy Chief Scientific Officer, 280
- Promotion of Dr. C. Timms (National Engineering Laboratory) to Deputy Chief Scientific Officer, 280
- Promotion of Dr. R. G. Hopkinson (Building Research Station) to Senior Principal Scientific Officer, 281
- Promotion of Dr. D. McLean (National Physical Laboratory) to Senior Principal Scientific Officer, 281
- Promotion of W. R. Piggott (Radio Research Station) to Senior Principal Scientific Officer, 281
- Moiré Fringes for Measurement and Control (prepared by the National Physical Laboratory and the National Engineering Laboratory), 376
- Report on Shipbuilding, 453
- Report for 1959 of the Water Pollution Research Board, 626
- The Investigation of Atmospheric Pollution, 626
- Thirty-first Annual Report of the Atmospheric Pollution Research Committee of the Fuel Research Board, 626
- Conference on Ergonomics in Industry, 633
- Appointment of Prof. M. V. Laurie as a member of the Steering Committee of the Forest Products Research Laboratory at Princes Risborough, 711
- Symposium at the National Engineering Laboratory on Flow Measurement in Closed Circuits, 786
- Test Track for the Road Research Laboratory (Dr. T. Lonsdale), 894
- Problems of Progress in Industry, No. 8, Ergonomics of Automation, 986

- Problems of Progress in Industry, No. 9, Automation and Skill (E. R. F. W. Crossman), 986
- The National Chemical Laboratory—Open Days (Dr. J. S. Anderson), 990
- Scientific and Industrial Research Organization (Australian Commonwealth): Collection of Australian Insects donated by Tarlton Rayment to the, 192
- Division of Fisheries and Oceanography, Technical Paper No. 9, The Concentration of Plankton Pigments in Australian Waters (Dr. G. F. Humphrey), 199
- Eleventh Annual Report (1958-59), 461
- Appointment of F. N. Ratcliffe as assistant chief of the Division of Entomology in Canberra, 537
- Appointment of Dr. H. E. Dadswell as chief of the Division of Forest Products, 988
- Scientific and Technical Advisory Committees: Government, 85
- Scientific and Technical Books: Recent, Supp. v, October 29; Supp. vi, November 26; Supp. vi, December 31
- Scientific and Technological Advancement: Prospects of, review by Sir Harry Melville, 807
- Scientific and Technological Man-power: Britain's (George Louis Payne), review by R. Brightman, 842
- Scientists: The Education of (British Association for the Advancement of Science, Section L (Education), Discussion on), 270
- Education of (Dr. James S. Tait), 1052
- Review of Studies in the Flow of Information among, Vol. I, Text; Vol. 2, Tables, review by Dr. D. J. Urquhart, 699
- Scientists in the Public Service: Special Promotions, 280
- Scientists, Pugwash International Conferences of: Conferences on Disarmament and World Security, 711
- Scientists (Consulting), Association of: Election of Officers for 1960-61, 193
- Scientists (Information), Institute of: Syllabus for Education in Information Work, 1153
- Scomberoxus saurus* (The Skipper), in the Southern North Sea and the Thames Estuary (Alwyne C. Wheeler and M. N. Mistakidis), 334
- Scopoletin in Leaves: Variations in, in relation to Chloride Treatment of Tobacco (H. D. Fowler), 1044
- Scopoletin and 6,7-Dimethoxycoumarin from *Dendrobium thyrsiflorum* (Reichb. f.): Ayapin, (T. C. Wrigley), 1108
- Scotland: Chemistry in, and its Pioneer Contributions to Textile Technology (Dr. A. Clow), 988
- Natural Resources in (Scottish Council's Committee on Natural Resources Symposium on), 106
- Scott, Dr. D.: Cover on River Bottoms, 76
- Scott, D., and others: Hydrogen Diffusion in Water-accelerated Rolling Surface Fatigue, 1182
- Scott, Dr. G. David: Packing of Spheres—Packing of Equal Spheres, 908
- Scott, G. R., and others: Blue Wildebeest and the Aetiological Agent of Bovine Malignant Catarrhal Fever, 1167
- Scott, Dr. Hugh: Obituary by E. B. Britton, 1070
- Scott, Dr. Richard: Automatic Equipment for the Collection and Processing of Data from Geiger-Müller Counters, 161
- Scott, T. G.: Intracellular Canals in Human Sweat Glands, 158
- Scott, W. E. (Haley, A. C. D. and) (advisory editors) Analogue and Digital Computers (Dr. M. G. Say, consulting editor), review by Dr. A. D. Booth, 970
- Scott, Prof. William Taussig: The Physics of Electricity and Magnetism, review by G. R. Noakes, 1061
- Scottish Council (Committee on Natural Resources): Symposium on Natural Resources in Scotland, 106
- Scottish Fisheries: Seals and (Dr. Bennet B. Rae), 774
- Scottish Museum (Royal): Exhibition on Atomic Energy, 193
- Scottish Society of the History of Medicine: Proceedings for 1959-60, 987
- Scottish Waters: A Pacific Salmon (*Oncorhynchus gorbuscha*) in (W. M. Shearer and Dr. E. Trewavas), 868
- Screening Technique for Photosynthetic Mutants in Unicellular Algae (Prof. R. P. Levine), 339
- Scrimshaw, Dr. N. S.: Appointed head of the Department of Nutrition, Food Science and Technology in the Massachusetts Institute of Technology, 279
- Sea in Motion: The Atmosphere and the—Scientific Contributions to the Rossby Memorial Volume (edited by Bert Bolin), review by Prof. P. A. Sheppard, 881
- Sea (Casplan): Fluctuations in the Level of the (B. G. Richter), 105
- Sea (Red) Hills: Autumn Temperatures in the (Dr. L. Berry and Prof. J. L. Cloudsley-Thompson), 843
- Sea (Southern North), and the Thames Estuary: The Skipper (*Scomberoxus saurus*) in the (Alwyne C. Wheeler and M. N. Mistakidis), 334
- Sea and Fresh Water: Productivity of the (British Association for the Advancement of Science, Section D (Zoology), Discussion on), 91
- Sea Birds (Charles Vaucher), translated by James Hogarth, review by Frances Pitt, 1139
- Sea Shells: Canadian Atlantic (E. L. Bousfield), 1155
- Sea Urchin, *Strongylocentrotus purpuratus*: Digestion of the Alga, *Macrocystis pyrifera*, by the (Reuben Lasker and Richard A. Boolootian), 1130
- Sea Urchin Eggs: Inhibitor of the Cytochrome Oxidase of Unfertilized (Rachelle Maggio, Franca Ajello and Prof. Alberto Monroy), 1195
- Seal, M.: Diamond Physics (Study of Graphitization), 368
- Seal (The Grey), and British Fisheries, 773
- Seals and Scottish Fisheries (Dr. Bennet B. Rae), 774
- Seals (Diving): Experiments with (Prof. R. J. Harrison), 1068
- Seaman, Dr. G. V. F., and others: A Sialomucopolypeptide Liberated by Trypsin from the Human Erythrocyte, 1011
- Search for New Antibiotics (Prof. G. F. Gause), review by Dr. P. W. Brian, 971
- Searching Mind in Medicine (William A. R. Thomson), review by Dr. Kathleen M. Hawkins, 832
- Season: Effect of, on the Follicle Stimulating Hormone and Luteinizing Hormone Potency of Sheep Anterior Pituitary Glands (J. S. M. Hutchinson and Dr. Hamish Robertson), 585
- Seasonal Factor in Influenza and Poliomyelitis: Virus Survival as a (J. H. Hammes, Prof. K. C. Winkler and S. M. Kool), 430
- Seasonal Variations in Fall-out: Tungsten-185 in Precipitation and the (Dr. A. Walton), 220
- Seasonal (Diurnal and) Density Variations in the Upper Atmosphere (Earth Satellite Observations and the Upper Atmosphere), (Dr. W. Priestner, H. A. Martin and K. Kramp), 202
- Sebba, Dr. F.: Organic Ion Flotation, 736
- Secondary School Examination Council: Examinations in Secondary Schools, Third Report, The General Certificate of Education and Sixth Form Studies, 610
- Secondary Schools: Examinations in, Third Report, The General Certificate of Education and Sixth Form Studies (Secondary School Examination Council), 610
- Secondary Structure of Ribonucleic Acid: Some Molecular Details of the (Prof. Jacques R. Fresco, Bruce M. Alberts and Prof. Paul Doty), 98
- Sécrétion d'enzymes par les Bactéries (Dr. M. R. Pollock), 627
- Secretion (Mammary), in Rats: Initiation of, by Electrical Stimulation of Nervous System (Dr. M. Maqsood and J. Meites), 752
- Secretion (Oral), of Fleas: Antigenic Property of the (Dr. E. Benjamini, Dr. Ben F. Feingold and Dr. L. Kartman), 959
- Security (World): Disarmament and (Pugwash International Conferences of Scientists Conferences on), 711
- Sedimentary Coastlines: Stabilization of (Dr. R. Silvester), 469
- Sediments in South Australia: Occurrence of Hydromagnesite in (Prof. A. R. Alderman and C. C. von der Borch), 931
- Sedum of the Trans-Mexican Volcanic Belt (Robert T. Clausen), review by N. Y. Sandwith, 264
- Seed Fertility: Development of Banana Fruits and (N. W. Simmonds), 278
- Seedling Roots of Leek and Broad Bean: A Comparison of Three Methods for the Assessment of Fungal Colonization of (J. H. Clarke and Dr. D. Parkinson), 166
- Seedlings (Wheat): Influence of Amino Triazole on the Chloroplast Pigments of (Prof. Frederick T. Wolf), 164
- Seeds, Dr. W. E.: Appointed to a Research Fellowship in the Department of Biomolecular Structure in the University of Leeds, 539
- Seeds (Germinating): Morphological Reactions of, as Criteria for the Plant Growth Regulating Activity of Auxin-Type Chemicals (J. Sudi, Gy. Josepovits and Gy. Matolcsy), 244
- Seeing the Very Small (Dr. V. E. Coslett), 1075
- Seepage Water: Some Water-Mites from (T. Gledhill), 1074
- Sekuzu, Ichiro, and others: Physico-chemical Properties of Purified Cytochrome c, 593
- Select Committee on Estimates: Fourth Report, together with part of the Minutes of Evidence taken before Sub-Committee D and an Appendix, Session 1959-60, Colonial Office, 523
- Selected Aboriginal and Indigenous Populations: Blood Groups of (Prof. John Buettner-Janusch, Henry Gershowitz, Leopold J. Pospisil and Peter Wilson), 153
- Selection (Natural), and the Sex Ratio (A. W. F. Edwards), 960
- Selection and Training of Computer Programmers (British Association for the Advancement of Science, Sub-section A* (Mathematics), Discussion on), 629
- Selective Inactivation of the Plasminogen Contaminant in Thrombin (Dr. Gabor Markus and Dr. Clara M. Ambrus), 582
- Selenite (Sodium): Toxicity of a Single Subcutaneous Dose of, in Pigs (Kerstin Orstadius), 1117
- Selenium (Urinary), and Dental Caries (Prof. D. M. Hadjilarkos), 677
- Self-Decomposition of Compounds labelled with Radioactive Isotopes (Dr. R. J. Bayly and Dr. H. Weigel), 384
- Self-Government: Local (Political and Economic Planning, Broadsheet No. 444), 21
- Self-Patterning: Impossible Magnetic-Field (John H. Mathews), 651; (Dr. D. Midgley), 651
- Self-Quenching Geiger-Müller Counters: Soft Ultra-violet Photons in (Prof. Rafi Mohammed Chaudhri and Rahmat Ullah), 131
- Sell, R. G. (Laner, Dr. S., and): Safety Propaganda in Industry, 898
- Selzer, H., and others: Reserpine Analogues, 1108
- Semenov, Academician N. N.: Some Problems of Chemical Kinetics and Reactivity, Vol. 1 (translated by Dr. J. E. S. Bradley), review by Prof. J. R. Partington, 699
- Semiconductivity in Hydrated Haemoglobin (Semiconductivity in Proteins and Haemoglobin), (Prof. D. D. Eley and D. I. Spivey), 725
- Semiconductivity in Proteins and Haemoglobin—Enhanced Semiconductivity in Protein Complexes (K. M. C. Davis, Prof. D. D. Eley and R. S. Smart), 724; Semiconductivity in Hydrated Haemoglobin (Prof. D. D. Eley and D. I. Spivey), 725
- Semiconductivity (Enhanced), in Protein Complexes (Semiconductivity in Proteins and Haemoglobin), (K. M. C. Davis, Prof. D. D. Eley and R. S. Smart), 724
- Semiconductors: Physics of (International Union of Pure and Applied Physics International Conference on), 632
- Super-Cell Structure of (Dr. B. R. Pamplin), 136
- Semi-microchemical Methods (Micro-and): An Introduction to (Norwood Technical College, London, Course on), 899
- Sen, B. R.: At the seventh Congress of the International Soil Science Society, 108
- Senile Dementia and Cerebral Oxygen Uptake measured on the Right and Left Sides (Irwin Feinberg, Mark H. Lane and Niels A. Lassen), 962
- Sense of Hearing (British Association for the Advancement of Science, Section I (Physiology), Discussion on), 268
- Sensitivity to Dihydrostreptomycin of Enterobacteriaceae Strains on Media containing Ammonium (Frits Ørskov and Ida Ørskov), 75
- Sensitivity (X-Ray), and Cell Stages in Malas of *Drosophila melanogaster*: Relation between (Ruth Savhagen), 429
- Sensitization of *Escherichia coli* to Gamma-Radiation by N-Ethylmaleimide (B. A. Bridges), 415
- Separated and Inactive A and B Chains: Regeneration of Insulin Activity from the (Dr. G. H. Dixon and Dr. A. C. Wardlaw), 721
- Separating the Different White Cells of Blood: An Albumin Gradient Method for, applied to the Concentration of Circulating Tumour Cells (A. I. Spriggs and R. F. Alexander), 863
- Separation: Efficiency of, in Buffered Paper Chromatography of Organic Electrolytes (Dr. Edward Soczewinski), 391
- Separation of Amino-acid Mixtures on Sulphonated Polystyrene Resin-loaded Papers (C. S. Knight), 739
- Separation of Human Serum Albumins (M. D. Poulik, W. W. Zuelzer and R. Meyer), 506
- Separation of Isotopes, review by Prof. E. H. S. Burhop, 262

- Separation of Reticulocytes by means of Multi-Layer Centrifugation (Prof. Eiichi Kimura, Tatsuo Suzuki and Yoshihiro Kinoshita), 1201
- Separation of Sphingosine and Dihydrosphingosine by Reversed Phase Paper Chromatography (Karl-Anders Karlsson), 312
- Separation (Liquid Chromatographic), of Mixtures of Polymers and Mineral Oil (P. I. Brewer), 934
- Separation Factor of Tritrated Water in Fractional Distillation (P. Avinur and Dr. A. Nir), 652
- Separators (Electromagnetic Isotopes), and Applications of Electromagnetically Enriched Isotopes (J. Koch, R. H. V. M. Dawson, M. L. Smith and W. Walcher), review by Prof. E. H. S. Burhop, 262
- Sequence Characteristics of a Bacterial Deoxyribonucleic Acid : Severe Distortion by 5-Bromouracil of the (Dr. Herman S. Shapiro and Prof. Erwin Chargaff), 62
- Sera (Anti-Gm) : Possible Origins of the (C. Ropartz, J. Lenoir, Y. Hemet and L. Rivat), 1120
- Sera (Human) with Antiserum : Immunoelectrophoresis of, to Raben Growth Hormone (Dr. B. J. Boucher), 1025
- Serengeti Shall Not Die (Dr. Bernhard and Michael Grzimek), review by Dr. A. S. Thomas, 830
- 'Serial Thrombin Time' Method for measuring Fibrinolytic Activity in Plasma (Dr. G. L. C. Ingram and Myrtle O. Matchett), 674
- Series (New), of Bronchodilators and Coronary Vasodilators : 1-3-Dialkyl-6-thioxanthines, a (A. K. Armitage and K. R. H. Wooldridge), 1107
- Serological Detection of a Virus in Cherry Trees with a Leaf Roll Disease (R. Cropley), 875
- Serotonin in Pineapple (D. W. Bruce), 147
- Serotonin (5-Hydroxytryptamine), in the Male Reproductive Tract of the Spiny Dogfish (Dr. T. Mann), 941
- Serum (Human) : Reduction of α -Ketobutyrate by (Dr. S. B. Rosalki and Dr. J. H. Wilkinson), 1110
- Serum Albumin (Human) : Binding of Haematin by (Prof. H. N. Little and Prof. J. B. Neilands), 913
- Serum Albumins (Human) : Separation of (M. D. Poulik, W. W. Zuelzer and R. Meyer), 506
- Serum Gamma-Globulin : A Rapid Method of Preparing Pure (Dr. D. R. Stanworth), 156
- Serum Inulin (Elevated), associated with Leucine-induced Hypoglycaemia (Angelo M. DiGeorge, Prof. Victor H. Auerbach and Dr. C. Charlton Mabry), 1036
- Serum Protein Abnormalities In 'Runted' Albino Rats (John S. Thompson and Clifford W. Gurney), 421
- Serum Protein Fractions : Interrelations of, in Normal Humans (Dr. C. J. Brackenridge), 154
- Serum Specificities of Higher Primates : Variations in the, detected by Two-Dimensional Starch-Gel Electrophoresis (Dr. Morris Goodman, Emily Poulik and M. D. Poulik), 78
- Serum (Stored) : Proteolysis in, and its Possible Significance in Cell Culture (Dr. Karl A. Piez, Dr. Vance I. Oyama, Dr. Leon Levintow and Dr. Harry Eagle), 59
- Servit, Dr. Z. : Prophylactic Treatment of Post-traumatic Audiogenic Epilepsy, 669
- Seshachar, Prof. B. R. : Appointment as professor of zoology in the University of Delhi, 707, work of, 707
- Settlement of Epiphytic Polyzoa : Effect of Extracts from Fucoids in promoting (Dr. D. J. Crisp and G. B. Williams), 1206
- Setzu, Andrea, and others : 5-Deoxycytidylic Acid-deaminating Activity in Human Gastric Mucosa and other Adult Mammalian Tissues, 146
- Severe Distortion by 5-Bromouracil of the Sequence Characteristics of a Bacterial Deoxyribonucleic Acid (Dr. Herman S. Shapiro and Prof. Erwin Chargaff), 62
- Sex in Granulopoietic Cells of Mice and Rats : Determination of (Dr. M. C. Berenbaum), 603
- Sex in the Hop : Changes in, caused by Plant Growth Substances (E. W. Weston), 81
- Sex in Man : The Cytogenetics of (Dr. C. E. Ford), 454
- Sex Differentiation of Flowering Plants : Gibberellin and (Dr. R. Herich), 599
- Sex Hormones as a Possible Factor Influencing the Level of Parasitization in Frogs (Dr. E. Lees and L. Bass), 1207
- Sex Ratio : Natural Selection and the (A. W. F. Edwards), 960
- Sexual Difference in the Concentration of Iodine-131 by the Submaxillary Gland of Mice (J. L. Llach, J. H. Tramezzani and J. R. Cordero Funes), 1204
- Sexual Differences (External), and their Significance in *Mormyrus kannume* Forskal, 1775 (Ronald B. Iles), 516
- Shadowing Material (A New), for Electron Microscopy (Dr. A. P. Murphy and Dr. J. F. Goodman), 689
- Shah, S. N. (Davies, Dr. D. Eurof, and) : Cathodic Cleaning of Metals before High-Temperature Oxidation, 138
- Shanes, Dr. A. M. : Mechanism of Change in Permeability in Living Membranes, 1209
- Shape Discrimination in *Octopus* : Theories of (Prof. J. A. Deutsch), 1090 ; (Dr. N. S. Sutherland), 1092
- Shape (Leaf-) in Hybrids (Dr. R. Melville), 23
- Shapiro, Dr. Herman S., and Chargaff, Prof. Erwin : Severe Distortion by 5-Bromouracil of the Sequence Characteristics of a Bacterial Deoxyribonucleic Acid, 62
- Shapley, Dr. Harlow : Biology of Space Travel (Probable Environment of other Planets), 1080
- Sharih, Dr. A., and others : Thalassemia in a Tibetan discovered during a Haemoglobin Survey among the Sherpas, 1121
- Sharp, J. A., and Burwell, Dr. R. G. : Interaction ('Paripolysis') of Macrophages and Lymphocytes after Skin Homografting or Challenge with Soluble Antigens, 474
- Sharpe, J. : Nuclear Radiation Measurement, review by W. R. Loosemore, 1143
- Shaw, H. K. Airy : Life in the Soil, review, 258
- Shaw, Dr. Sidney : Title of reader in haematology in the University of London (at Charing Cross Hospital Medical School) conferred on, 279
- Shaylor, H. R. : Appointed Staff Fellow in nuclear physics at the University of Birmingham, 539
- Shearer, W. M., and Trowaves, Dr. E. : A Pacific Salmon (*Oncorhynchus gorbuscha*) in Scottish Waters, 868
- Sheaths (Myelin) : Neurokeratin Network of (Prof. M. A. MacConaill and E. Gurr), 1122
- Sheep : Uptake of Magnesium-28 by the Skeleton of a (Alexander C. Field), 1205
- Sheep Anterior Pituitary Glands : Effect of Season on the Follicle Stimulating Hormone and Lutemizing Hormone Potency of (J. S. M. Hutchinson and Dr. Hamish Robertson), 585
- Sheibani, Dr. A. A. : Nuclear Science (Iranian Radioactive Prospecting Project), 541
- Shells : Canadian Atlantic Sea (E. L. Bousfield), 1155
- Shepard, Harold H. (edited by) : Methods of Testing Chemicals on Insects, Vol. 2, review by Dr. W. A. L. David, 1059
- Sheppard, Prof. P. A. : Rossby Posthumously Honoured, review, 881
- Sheppard, Prof. P. A. (edited by Dr. F. N. Frenkel and) : Atmospheric Diffusion and Air Pollution—Proceedings of a Symposium held at Oxford, 1958 (Advances in Geophysics, Vol. 6), review by Dr. A. C. Best, 837
- Sherf, Prof. Arden F. (Chupp, Prof. Charles, and) : Vegetable Diseases and their Control, review by Dr. W. G. Keyworth, 350
- Sherpas : Thalassemia in a Tibetan discovered during a Haemoglobin Survey among the (F. S. Jackson, Dr. H. Lehmann and Dr. A. Sharih), 1121
- Shettles, Prof. Landrum B. : Nuclear Structure of Human Spermatozoa, 918
- Shewan, Dr. J. M. : *Pseudomonas* and *Achromobacter*, 26
- Shield, J. W., and Woolley, Patricia : Gestation Time for Delayed Birth in the Quokka, 163
- Shields, W. R., and others : Mass-Spectrometer Investigation of the Atomic Weight of Silver, 1156
- Shimizu, Prof. Nobuo, and others : Histochemical Demonstration of Aromatic Monoamine in the Locus Coeruleus of the Mammalian Brain, 326
- Shimura, Prof. K. (Sagisaka, S., and) : Mechanism of Activation and Reduction of α -Aminoadipic Acid by Yeast Enzyme, 1189
- Shipbuilding (Department of Scientific and Industrial Research Report on), 453
- Shipbuilding and Research : British, 537
- Ships under Way : Porpoises and the Bow-Riding of (Andrew A. Fejer and Richard H. Backus), 700
- Shock Excitation of Solid Aromatic Hydrocarbons (Prof. R. W. Nicholls and M. D. Watson), 568
- Shockey, Dr. W. : Elected an Honorary Fellow of the National Institute of Sciences of India, 365
- Physics of Semiconductors (Phenomena associated with Avalanche Breakdown in p-n Junctions induced by High Electric Fields), 632
- Shockey, Dr. W., and Hubner, K. : Physics of Semiconductors (An n-p-n Structure to demonstrate Phonon Drag on Electrons), 632
- Shoenberg, Dr. D. : Appointed Guthrie Lecturer for 1961 of the Institute of Physics and the Physical Society, 710
- Shooter, Dr. K. V. (Bianchi, Dr. P. A., and) : Ultracentrifugation (Study of the Sedimentation Characteristics of Deoxyribonucleic Acid by the Ultra-violet System), 635
- Shorley, Patricia G., and Collier, Dr. H. O. J. : Bradykinin—Direct Comparisons of the Synthetic Nonapeptide with Trypsin Bradykinin, 999
- Short, R. V. : Identification of 19-Norandrostenedione in Follicular Fluid, 232
- Short-Period Time Variations of Extensive Cosmic Ray Showers (Donald G. Yerg and Phyllis M. Gildersleeve), 651
- Short-Term Weaning : Effects of, on the Acid-soluble Ribonucleotides of Rat Mammary Gland (Dr. D. Y. Wang), 1109
- Shortage of Graduate Biochemists, 898
- Showers (Cosmic Ray) : Short-Period Time Variations of Extensive (Donald G. Yerg and Phyllis M. Gildersleeve), 651
- Shreir, L. L. (Lakhiani, D. M., and) : Crystallization of Amorphous Niobium Oxide during Anodic Oxidation, 49
- Shrinkage Temperature of Collagen : Hydroxyproline and the (Dr. J. H. Bowes and Dr. J. A. Moss), 1120, (Dr. B. J. Rigby and Dr. J. D. Spikes), 1120
- Shrubs and Trees : Ferns, Mosses, review by B. L. Burtt, 817
- Garden (S. G. Harrison), review by B. L. Burtt, 817
- Shulman, Prof. Sidney : Identification of Ultracentrifugal Components in Human Plasminogen Preparations, 161
- Sialidase : Influenza Virus (Dr. Calderon Howe, Lucille T. Lee and Harry M. Rose), 251
- Sialomucopolysaccharide Liberated by Trypsin from the Human Erythrocyte (G. M. W. Cook, Dr. D. H. Heard and Dr. G. V. F. Seaman), 1011
- Siamese Fighting Fish : Muscular Dystrophy in the, as an Aberration of the Connective Tissue (Prof. A. Stolk), 751
- Siberian Arctic—the Story of the Siberia Company (Jonas Lied), review by L. M. Forbes, 841
- Sickle Cell Trait in the Bantus of West Belgian Congo : Glucose-6-phosphate Dehydrogenase Deficiency, Haptoglobin Groups, Blood Groups and (Prof. J. Sonnet and Dr. J. L. Michaux), 504
- Sides (Right and Left) : Senile Dementia and Cerebral Oxygen Uptake measured on the (Irwin Feinberg, Mark H. Lane and Niels A. Lassen), 962
- Siegel, Edward, and others : Early Incorporation of Sulphur-35 Sodium Sulphate into Plasma Proteins of Man, 1125
- Siegmán, M., and others : Storage and Release of Catecholamines, and the Occurrence of a Specific Submicroscopic Granulation in Hearts of Cyclostomes, 324
- Signal Detection : Statistical Theory of (Dr. Carl W. Halstrom), review by Dr. P. Whittle, 827
- Signal Establishment (Admiralty) : Promotion of R. Benjamin to Deputy Chief Scientific Officer, 280
- Signal Strength (Electron Spin Resonance), from Guinea Pig Adrenals : Correlation of Biological Activity and the (Frank K. Truby and Dr. Joseph W. Goldzieher), 1068
- Signals and Statistics, review by Dr. P. Whittle, 827
- Significance in *Mormyrus kannume* Forskal, 1775 : External Sexual Differences and their (Ronald B. Iles), 516
- Significance (Possible), in Cell Culture : Proteolysis in Stored Serum and its (Dr. Karl A. Piez, Dr. Vance I. Oyama, Dr. Leon Levintow and Dr. Harry Eagle), 59
- Silica Glass : Strength of (Dr. I. Náray-Szabó and J. Ladik), 226
- Silicate (Calcium), 'Phase Z' : New Data for the (Dr. D. M. Roy, Dr. J. A. Gard, A. W. Nicol and Dr. H. F. W. Taylor), 1187

- Silicate (Lead) Glass: Radiation-induced Defects in (R. S. Barker, D. A. Richardson, E. A. G. McConkey and R. E. Yeadon), 1181
- Silicates: Formation of Hydrogarnet by Chemical Reaction among Calcium Carbonate, Ammonium Chloride and some (Prof. Toshio Sudo, Satoru Ueda and Shigeki Iwamoto), 223
- Silicates (Synthetic and Natural): A Plate Method for Studying the Breakdown of, by Soil Bacteria (Dr. D. M. Webley, Dr. R. B. Duff and W. A. Mitchell), 766
- Silicic Acid Columns: Heterogeneity of Liver Lecithin isolated by Chromatography on (P. M. Harris, D. S. Robinson and G. Getz), 742
- Silicon γ -Ray Spectrometer (P. E. Gibbons and D. C. Northrop), 803
- Silicosis: Some Oxidative and Hydroxylative Actions of Quartz—their Possible Relationship to the Development of (L. W. Marasas and Dr. J. S. Harrington), 1173
- Silk Flags: Treatment of Deteriorating (Harry Wandrus), 1155
- Silkworm, *Bombyx mori*: Blood Trehalose and Fat-Body Glycogen in the (Yasuhiro Horie), 583
- Sillen, Dr. L. G.: Co-ordination Chemistry (Varied Hydrolysis Reactions of Metal Ions in Aqueous Solution), 715
- Silver: Mass-Spectrometer Investigation of the Atomic Weight of (W. R. Shields, D. N. Craig and V. H. Diebeler), 1156
- Silver in Lead Concentrates: Determination of, by Atomic Absorption Spectroscopy (B. S. Rawling, M. C. Greaves and M. D. Amos), 137
- Silver Iodide Sol: Preparation of, by Ion-exchange Resin (P. Van der Wee), 655
- Silver Medal of the Liverpool Geological Society awarded to Prof. Alan Wood, 1075
- Silvester, Dr. N. R., and Burge, Dr. R. E.: Theoretical Limiting Thicknesses for Single Scattering in Electron Microscopy, 641
- Silvester, Dr. R.: Stabilization of Sedimentary Coastlines, 469
- Simoy, Prof. T. S.: Genetic Anthropology, review, 260
- Simic, M., and others: Radiation-induced Carboxylation of Organic Compounds—Formation and Reactions of the Carboxyl Radical Ion, 1019
- Simmonds, N. W.: Development of Banana Fruits and Seed Fertility, 278
- Simms, D. J.: Appointed lecturer in mathematics at the University of Glasgow, 988
- Simons, Donald G., and others: Spectrum of Radiation Background under Water, 266
- Simons, Dr. E. L.: The Paleocene Pantodonts, 200
- Simple Diatomic Molecules on Metals: Heats of Chemisorption of (M. Wyn Roberts), 1020
- Simple Method for Making Preparations: Mammalian Cell Chromosome Counts—a (Dr. N. S. Fechner), 247
- Simpson, Prof. S.: Synthesis of Applied Palaeontology, review, 818
- Sims, Dr. G. D., and others: Operation of the Backward-Wave Oscillator, 803
- Simultaneous Application of Townsend and Streamer Theory (Dr. A. E. D. Heylen), 734
- Simultaneous Determination of Scandium and Dysprosium by Neutron Activation followed by γ -Ray Spectrometry (Minoru Okada), 575
- Singer, Dorothea Waley: History and Philosophy of Science, review, 439
- Singer, Prof. S. F.: Recent Advances in Aeronomy (Distribution of Density in the Exosphere), 712
- Use of an Artificial Satellite to test the Clock 'Paradox' and General Relativity, 1014
- Single Crystals (Palladium): Crucible Material for the Growth of (W. J. Fredericks and R. A. Pasternak), 400
- Single Cultured Cardiac Muscle Cells: Specificity of the Effects of Cardiac Glycosides on the Rhythmic Contraction of (Prof. Albert Wollenberger and Willi Halle), 1114
- Single Scattering in Electron Microscopy: Theoretical Limiting Thicknesses for (Dr. N. R. Silvester and Dr. R. E. Burge), 641
- Single Subcutaneous Dose of Sodium Selenite in Pigs: Toxicity of a (Kerstin Orstadius), 1117
- Singleton, W. T.: Ergonomics in Industry, 634
- Sinhala Combative, Field and Aquatic Sports and Games: Some (Dr. P. E. P. Deraniyagala), 191
- Sinno, K. (Jacobs, Prof. J. A., and): Some Characteristics of Geomagnetic Micropulsations (Pc), 285
- Sirlin, Dr. J. L.: Title of Research Fellow in the Department of Animal Genetics in the University of Edinburgh conferred on, 988
- β -Sitosterol and other Lipids: Metabolism of, in the Presence of Acetate-2- ^{14} C by Blowfly Larvae (E. Kodicek and Z. H. Levinson), 1023
- Sivertz, Dr.: At the Tenth Canadian High Polymer Forum (Natural and Synthetic Macromolecules), 456
- Sixth Form: Arts and Science Sides in the (University of Oxford Department of Education), 610
- Sixth Form Studies: The General Certificate of Education and (Examinations in Secondary Schools, Third Report), (Secondary School Examination Council), 610
- Skaugstad, Charles, and others: Growth of Mouse Femurs during Continual Centrifugation, 151
- Skeletal Muscle Fibre (Frog): Electrical Inexcitability of the Synaptic Membrane in the (Prof. Robert Werman), 149
- Skeleton of a Sheep: Uptake of Magnesium-28 by the (Alexander C. Field), 1205
- Skill: Automation and (E. R. F. W. Crossman), (Problems of Progress in Industry, No. 9), (Department of Scientific and Industrial Research), 986
- Skin (Isolated Frog): Active Transport of Sodium by, in relation to Metabolism of Acetate labelled with Carbon-14 (J. T. Van Bruggen and K. Zerahn), 499
- Skin Grafts (Maternal), in Rabbits: Tolerance to, induced by Hyaluronidase (Dr. Paul Nathan, Dr. Eduardo Gonzalez and Prof. Benjamin F. Miller), 77
- Skin Homografting or Challenge with Soluble Antigens: Interaction ('Peripiles') of Macrophages and Lymphocytes after (J. A. Sharp and Dr. R. G. Burwell), 474
- Skin Homografts in the Rat: A Composite Response of (John Anderson), 679
- Skinner, Prof. B. F.: Verbal Behaviour, review by P. R. F. Clarke, 814
- Skipper (*Scomberox saurus*) in the Southern North Sea and the Thames Estuary (Alwyne C. Wheeler and M. N. Mistakidis), 334
- Skudrzyk, Dr. E. J.: Sound Propagation in the Atmosphere (The Fundamentals of Sound Scattering and Signal Fluctuations in an Inhomogeneous or Turbulent Motion), 993

- Southorn, Dr. W. A. : Complex Particles in Hevea Latex, 165
- Soviet Photographs : Moon Maps, with a Chart showing the Other Side of the Moon based upon (H. P. Wilkins), review by Simone Daro Gossner, 88
- Space : The Exploration of—a Symposium on Space Physics, 1959 (sponsored by the United States National Academy of Sciences, the National Aeronautics and Space Administration, and the American Physical Society), (edited by Robert Jastrow), review by D. G. King-Hele, 1058
- Space Research, review by D. G. King-Hele, 1058
- Radio Techniques and (British Institution of Radio Engineers Convention on), 1156
- Space Science : Advances in (edited by Frederick I. Ordway), Vols. 1 and 2, review by Prof. D. R. Bates, 885
- Space Travel : Biology of (Institute of Biology Symposium on), 1078
- Spar, Prof. Jerome (Feely, Dr. Herbert W., and) : Tungsten-185 from Nuclear Bomb Tests as a Tracer for Stratospheric Meteorology, 1062
- Spaul, Prof. E. A. : Title of emeritus professor of zoology in the University of Leeds conferred on, 539
- Speakman, Prof. J. B., and others : Plasticity of Wool, 69
- Speakman, J. C. (Brand, J. C. D. and) : Molecular Structure—the Physical Approach, review by Dr. D. W. J. Cruickshank, 696
- Special Education : Statistics on (Unesco), 994
- Species : Darwin's Fourth Notebook on the Transmutation of (edited by Sir Gavin de Beer), 1154
- Species (Threatened) : A Look at (L. M. Talbot), 1155
- Species (Two), of Monkeys : β -Globulin Variants in (L. Y. C. Lai and Dr. R. L. Kirk), 673
- Specific Action on the Central Nervous System by the Esters of some Plant Growth Regulator Acids : Evidence of a (Dr. J. Thuillier, Germaine Thuillier and P. Rumpf), 152
- Specific Activities of Acid-soluble Nucleotides in Hind-Leg Muscles of Mice with Dystrophia Muscularis (Dr. Michael C. Zymaris, Dr. Abraham Saifer and Dr. Bruno W. Volk), 323
- Specific Chromosome Abnormality (A Possible), in Human Chronic Myeloid Leukaemia (A. G. Baikie, W. M. Court-Brown, Karin E. Buckton, D. G. Harnden, Patricia A. Jacobs and Isabel M. Tough), 1165
- Specific Fall-out Activity in Precipitation as a Function of Sampling Height (A. Aarkrog), 462
- Specific Protein of Legumes which Reacts with Animal Proteins (S. Nakamura, K. Tanaka and S. Murakawa), 144
- Specific Submicroscopic Granulation in Hearts of Cyclostomes : Storage and Release of Catecholamines, and the Occurrence of a (E. Östlund, G. Bloom, J. Adams-Ray, M. Rützn, M. Siegmán, H. Nordenstam, F. Lishajko and Prof. U. S. von Euler), 324
- Specificities (Serum), of Higher Primates : Variations in the, detected by Two-Dimensional Starch-Gel Electrophoresis (Dr. Morris Goodman, Emily Poulik and M. D. Poulik), 78
- Specificity of the Effects of Cardiac Glycosides on the Rhythmic Contraction of Single Cultured Cardiac Muscle Cells (Prof. Albert Wollenberger and Willi Halle), 1114
- Specificity and Inheritance of Antibody Response—a Possible Steering Mechanism (Dr. B. Cindader), 619
- Specificity (Host-) in the Tetracyclides : The Intestine in Members of the Genus *Raja* and (Dr. H. Harford Williams), 514
- Specificity (Host), of Two *Xanthomonas* Species (C. Logan), 479

- Spectra of Tetrahedral Inorganic Complexes (S. Buffagni and T. M. Dunn), 937
- Spectra (Absorption), of Copper (II) and Nickel (II) Complexes (Dr. J. Császár and J. Balog), 402
- Spectra (Nuclear Magnetic Resonance), of Solids: Fine Structure of the—Chemical Shift Structure of the Spectrum of Phosphorus Pentachloride (Prof. E. R. Andrew, A. Bradbury, Dr. R. G. Eades and G. J. Jenks), 1096
- Spectra (Ultra-violet Absorption), of the Molecules H_2O , HDO and D_2O (Prof. W. C. Price, P. V. Harris, Dr. G. H. Beaven and Dr. E. A. Johnson), 45
- Spectral Reflectivity of Ore Minerals (I. Gray and Dr. A. P. Millman), 1100
- Spectro-Analytical Results: Evaluation and Presentation of (A. B. Calder), 277
- Spectrometer: A Silicon γ -Ray (P. E. Gibbons and D. C. Northrop), 803
- Spectrometer (Mass)—Investigation of the Atomic Weight of Silver (W. R. Shields, D. N. Craig and V. H. Diebeler), 1156
- Spectrometry (γ -Ray): Rapid Analysis of Erbium by Neutron Activation followed by (Minoru Okada), 52
- Simultaneous Determination of Scandium and Dysprosium by Neutron Activation followed by (Minoru Okada), 575
- Spectrophotometric Evidence: Use of, for Protein-Dye Binding (Dr. C. M. French and R. Pritchard), 228
- Spectroscopy: Molecular Structure and (Ohio State University Symposium on), 988
- Ninth International Colloquium on, 193
- Spectroscopy Conference (Western): Eighth Annual (Western Spectroscopy Association), 627
- Spectroscopy (Atomic Absorption): Determination of Silver in Lead Concentrates by (B. S. Rawling, M. C. Greaves and M. D. Amos), 137
- Spectroscopy Association (Western): Eighth Annual Western Spectroscopy Conference, 627
- Spectrum of Phosphorus Pentachloride: Fine Structure of the Nuclear Magnetic Resonance Spectra of Solids—Chemical Shift Structure of the (Prof. E. R. Andrew, A. Bradbury, Dr. R. G. Eades and G. J. Jenks), 1096
- Spectrum of Radiation Background under Water (Gordon K. Riel, John P. Dolfus and Donald G. Simons), 266
- Spectrum (Ammonia): Line Broadening in the (J. A. Fulford), 1097
- Spectrum (Infra-Red), of Praseodymium Nitrate (Dr. F. Vratney, Dr. M. Tsai and F. Gugliotta), 484
- Specular Reflections: Effect of, on Radiation Flux from a Heated Tube (Sir K. S. Krishnan), 652
- Speed (High) Computation Methods and Machines (Indian Society of Theoretical and Applied Mechanics Symposium on), 24
- Speed (Supersonic): Some Physical Problems in Travelling at (Dr. F. P. Bowden), 454
- Spencer, Sir Thomas: Computer Service Centre at Woolwich Polytechnic, London, opened by, 708
- Spendiarov Prize awarded to Dr. Sigurdur Thormannsson, 902
- Sperm (Human): Prolonged Survival of, in Chemically Defined Media at Room Temperatures (Prof. Charles Norman, Erwin Goldberg, I. D. Porterfield and C. E. Johnson), 760, *erratum*, 899
- Spermatozoa (Human): Nuclear Structure of (C. van Duin, jun.), 916; (Prof. Landrum B. Shettles), 918
- Spermine: Action of, on Soluble Ribonucleic Acid and some Polynucleotides—Spermine Fractionation of Soluble Ribonucleic Acid of Rabbit Liver (Dr. G. L. Cantoni), 300; Solubility of Complexes of Polynucleotides with Spermine (S. Lee Huang and Dr. G. Felsenfeld), 301
- Solubility of Complexes of Polynucleotides with (Action of Spermine on Soluble Ribonucleic Acid and some Polynucleotides), (S. Lee Huang and Dr. G. Felsenfeld), 301
- Spermine Fractionation of Soluble Ribonucleic Acid of Rabbit Liver (Action of Spermine on Soluble Ribonucleic Acid and some Polynucleotides), (Dr. G. L. Cantoni), 300
- Spermiogenesis (Atypical), in *Thermobia domestica*, a Thysanuran Insect (Dr. S. R. Bawa), 1132
- Spermiogenesis (Thysanuran): Electron Microscopy of (R. S. Mathur), 164
- Spheres: Packing of—Packing of Equal Spheres (Dr. G. David Scott), 908; Co-ordination of Randomly Packed Spheres (Prof. J. D. Bernal and J. Mason), 910

- Structure : Molecular—the Physical Approach (J. C. D. Brand and J. C. Speakman), review by Dr. D. W. J. Cruickshank, 696
- Structure of *Acrocomia* Fruit (Dr. J. G. Vaughan), 81
- Structure of Bacteria, review by L. B. Quessell, 259
- Structure of Isometamidium (M. and B. 4180A), 7-m-Aminodiphenyldiazoxamino-2-amino-10-ethyl-9-phenylphenanthridinium Chloride Hydrochloride, the Red Isomer present in Metamidium (S. S. Berg), 1106
- Structure of Scientific Thought, an Introduction to Philosophy of Science (Dr. Edward H. Madden), review by F. I. G. Rawlins, 831
- Structure of the Trinuclear Titanium (IV) Alkoxides (R. L. Martin and G. Winter), 313
- Structure of the Walls of the Bile 'Canaliculi' in Mammalian Liver Cells (J. M. Davis), 1123
- Structure (Chemical Shift), of the Spectrum of Phosphorus Pentachloride : Fine Structure of the Nuclear Magnetic Resonance Spectra of Solids—(Prof. E. R. Andrew, A. Bradbury, Dr. R. G. Eades and G. J. Jenks), 1096
- Structure (Crystal), of $Ba_{1-x}Te_{2x}$ (Francis Galasso and Prof. Lewis Katz), 1099
- Structure (Crystal), of Orthorhombic Cobalt Molybdate (G. W. Smith), 306
- Structure (Crystal), of 1-3-7-9 Tetramethyluric Acid and the Molecular Packing in Hydroxymethyl Purine Crystals (P. De Santis, E. Giglio and Dr. A. M. Liguori), 46 ; (Dr. D. June Sutor), 47
- Structure (Fine), of the Neurosecretory System in Lepidoptera (Junko Nishitsutsuji-uwo), 953
- Structure (Fine), of the Nuclear Magnetic Resonance Spectra of Solids—Chemical Shift Structure of the Spectrum of Phosphorus Pentachloride (Prof. E. R. Andrew, A. Bradbury, Dr. R. G. Eades and G. J. Jenks), 1096
- Structure (Molecular), and Spectroscopy (Ohio State University Symposium on), 988
- Structure (Nuclear), of Human Spermatozoa (C. van Duin, Jun.), 916 ; (Prof. Landrum B. Shettles), 918
- Structure (Secondary), of Ribonucleic Acid : Some Molecular Details of the (Prof. Jacques R. Fresco, Bruce M. Alberts and Prof. Paul Doty), 98
- Structure (Super-Cell) of Semiconductors (Dr. B. R. Pamplin), 136

- Structure and Function : Biological (International Union of Biological Sciences and the International Union of Biochemistry Joint Symposium on), 1160
- Structures (Crystal), of 1-Chloro-2,4-Dinitrobenzene and 1-Bromo-2,4-Dinitrobenzene (K. J. Watson), 1102
- Structures (Non-metallic Layer) : Dislocations in (J. R. Bristow and B. L. Rees), 44
- Stuckenrath, jun., Robert (Ralph, Elizabeth K., and) Carbon-14 Measurements of Known Age Samples, 185
- Student Grants for University Education, 1
- Students : Government Grants to University and other, 897
- Grants to—Report of the Committee appointed by the Minister of Education and the Secretary of State for Scotland (Ministry of Education—Scottish Education Department), 1
- Procedure for Admission of (Association of Universities of the British Commonwealth), 716
- Students (Commonwealth), in Britain : Science and Technology for, 897
- Students (Overseas), in Britain (British Council), 897
- Studies on Agar Gel Electrophoresis (Dr R. J. Wieme), review by Dr. R. Conden, 8
- Studies in the Flow of Information among Scientists : Review of, Vol. 1, Text, Vol. 2, Tables, review by Dr. D. J. Urquhart, 699
- Studies in Linear and Non-Linear Programming (Prof. Kenneth J. Arrow, Prof. L. Hurwicz and Hirofumi Uzawa), review by Prof. L. S. Goddard, 6
- Studies on Phycobilin Formation with Mutants of *Cyanidium caldarium* (Kenneth E. Nichols and Lawrence Bogorad), 870
- Studies (Electron Paramagnetic Resonance), of Stable Free Radicals in Lignins and Humic Acids (Dr R. W. Rex), 1185
- Studies (Photographic), of Fish Populations (R. E. Craig and R. Priestley), 333
- Studies (Sixth Form) : The General Certificate of Education and (Examinations in Secondary Schools, Third Report), (Secondary School Examination Council), 610
- Studies (X-Ray Diffraction), of Thermally Decomposed Permanganates (P. J. Herley and Dr. E. G. Proust), 717
- Study of Development and Growth, United States Society for the : Election of Officers for 1960-61, 367
- Study of Elementary Particles by the Photographic Method (Prof. C. F. Powell, P. H. Fowler and Dr. D. H. Perkins), review by Prof. G. D. Rochester, 175
- Study in Forensic and Clinical Psychology : Delinquency and Parental Pathology—a (Dr Robert G. Andry), review by John Gittins, 527
- Study of the Organization Man in Russian Industry : The Red Executive—a (Dr. David Granick), review by T. H. Hawkins, 7
- Study of Sub-Atomic Phenomena by the Nuclear Emulsion, review by Prof. G. D. Rochester, 175
- Study of Thiamine Deficiency : A New Approach to the (Dr. C. C. Liang), 660
- Study of Vision : Progress in the, review by Prof. George Wald, 261
- Study (An Electron Microscope), of Graphite Oxidation (J. A. Hedley), 44
- Study (X-Ray Diffraction), of Acellular Teleost Bone (Prof. Melvin L. Moss and Dr. Aaron S. Posner), 1037
- Studying Amino-Acid Activation in Crude Tissue Extracts : A Method for (G. Coleman and Dr. W. H. Elliott), 64
- Studying the Breakdown of Synthetic and Natural Silicates by Soil Bacteria : A Plate Method for (Dr. D. M. Wembley, Dr. R. B. Duff and W. A. Mitchell), 766
- Sturmer, Dr. E. (Konzett, Prof. H., and) : Bradykinin—Synthetic Bradykinin, its Biological Identity with Natural Pure Trypsin Bradykinin, 998
- Stutman, Joel M., and others : Hydrogen-bonding in Calcium-deficient Hydroxyapatites, 486
- Stylets of Mature Apterous Viviparae of *Myzus persicae* : Effect of amputating (R. H. E. Bradley), 337
- Styrene (α -Methyl), and β -Pinene : Radiation-induced Ionic Reactions—the Retardation of the Homopolymerizations of, by Water (T. H. Bates, J. V. F. Best and T. Francon Williams), 469
- Sub-Atomic Phenomena : The Study of, by the Nuclear Emulsion, review by Prof. G. D. Rochester, 175
- Subcutaneous Dose (Single), of Sodium Selenite in Pigs : Toxicity of a (Kerstin Orstadius), 1117
- Subject Catalogues—Headings and Structure (Library Association), review, 842
- Subjects for Research and Development : The Choice of (Sir Harold Hartley), 1055
- Sub-Line of Mouse Sarcoma-180 : Development of a, capable of Growing in Pyridoxine-deficient Animals (Dr. Enrico Mihich and Dr. Charles A. Nichol), 379
- Submaxillary Gland of Mice : A Sexual Difference in the Concentration of Iodine-131 by the (J. L. Llach, J. H. Tramezzani and J. R. Cordero Funes), 1204
- Submicroscopic Granulation (Specific), in Hearts of Cyclostomes : Storage and Release of Catecholamines, and the Occurrence of a (E. Östlund, G. Bloom, J. Adams-Ray, M. Ritzén, M. Siegmán, H. Nordenstam, F. Lishajko and Prof. U. S. von Euler), 324
- Submillimetre Waves by Harmonic Generation from Cold Cathode Arcs (Dr. K. D. Froome), 43
- Subrahmanyam, S. V. : Velocity of Ultrasonic Waves in Aqueous Solutions of Zinc Halides, 570
- Substance (Growth-promoting) : Direct Transmission of a, from Strawberry to Pea (P. A. Thompson), 682
- Substances (Growth) : Effect of, on the Osmotic Value of Pea Stem Sections (Shizuko Yoda and Joji Ashida), 600
- Substances (Growth-stimulating) : Alkoxylglycerols as (Dr. Astrid Broholt), 591
- Substances (Inorganic) : Fluorescence of Organic Traces in (Prof. K. Przibram), 657
- Substances (Plant Growth) : Changes in Sex in the Hop caused by (E. W. Weston), 81
- Substrates (Exogenous and Endogenous) : Different Action of 2,4-Dinitrophenol on the Oxidation of, by Baker's Yeast (Prof. A. O. M. Stoppani, Dr. E. H. Ramos and I. Widuczynski), 1168
- Sub-Unit (Black), of the Crystallographic Model of Horse Haemoglobin : Identification of the, with the Valyl-Glutamyl Polypeptide Chain (Dr. David B. Smith and Dr. M. F. Perutz), 406
- Sub-Units : Enzymatic Degradation of Deoxyribonucleic Acid into (Giorgio Bernardi, Madeleine Champagne and Dr. Charles Sadron), 228
- Succinate : Energetic Aspects of the Mitochondrial Oxidation of (Dr. Giovanni Felice Azzone, Dr. Lars Ernster and Dr. Martin Klingenberg), 552
- Succinate and Adenine Nucleotides : Abolition by 2,4-Dinitrophenol of the Protective Effect of, on the Onset of the Thyroxine-induced Swelling of Liver Mitochondria (Dr. P. Emmelot), 1197
- Suckled Calf (New-born) : β -Lactoglobulins in the Urine of the (Dr. Alan E. Pierce), 940
- Sucrose Crystals (H. E. C. Powers), 289
- Sudi, J., and others : Morphological Reactions of Germinating Seeds as Criteria for the Plant Growth Regulating Activity of Auxin-Type Chemicals, 244
- Sudo, Prof. Toshio, and others : Formation of Hydrogarnet by Chemical Reaction among Calcium Carbonate, Ammonium Chloride and some Silicates, 223
- Sudre, René : Treatise on Parapsychology (translated by C. E. Green), review by Dr. E. J. Dingwall, 177
- Sugar Cane : Protein from (Dr. D. H. Parish), 601
- Sugar-Cane Frog-hopper : Number of Nymphal Instars of the (Dr. D. W. Fewkes), 167
- Sulitzeanu, Dr. D. : Localization of Radioactivity in Tumours of Mice injected intravenously with Killed, Radioiodinated *Brucella abortus*, 757
- Sullivan, Dr. E. P. A. (Huang, Dr. H. H., and) : Atomic Polarizations of Chloro-, Bromo- and Iodo-benzene, 1104
- Sullivan, M. F. (Marks, S., and) : Tumours of the Small Intestine in Rats after Intestinal X-Irradiation, 953
- Sulphate (Calcium Chondroitin) : Crystallinity of (Prof. F. A. Bettelheim and D. E. Philpott), 654
- Sulphate (Sulphur-35 Sodium) : Early Incorporation of, in Plasma Proteins of Man (Dr. Bernard A. Sachs, Edward Siegel and Joseph V. Marino), 1125
- Sulphide Additives (Inorganic) : Frictional Properties of Molybdenum Disulphide Films containing (A. J. Halmor and C. S. Oliver), 308
- Sulphonated Polystyrene Resin-loaded Papers : Separation of Amino-Acid Mixtures on (C. S. Knight), 739
- Sulphur : Formation of Vibrationally Excited Carbon Monosulphide and, by the Flash Photolysis of Carbon Disulphide (Dr. A. B. Callear and Prof. R. G. W. Norrish), 53
- Sulphur Dioxide : Detection of Photochemical Oxidation of, by Condensation Nuclei Techniques (S. B. Dunham), 51
- Sulphur Tetrafluoride : Dipole Moments of Fluorine Monoxide and (R. E. Dodd and R. Little), 737
- Sulphur-35 Sodium Sulphate : Early Incorporation of, in Plasma Proteins of Man (Dr. Bernard A. Sachs, Edward Siegel and Joseph V. Marino), 1125
- Summer School on Fast Reactions (University of Cambridge Physical Chemistry), 899
- Sumner, Prof. William Graham : Folkways, a Study of the Sociological Importance of Usages, Manners, Customs, Mores and Morals, review by Dr. E. J. Dingwall, 613
- Sumner, Dr. W. L. : Science and Liberal Education, 614
- Sun : Mass Density near the (E. R. Hill), 111 : (J. H. Oort), 112
- Sun Navigation by Birds (Prof. R. J. Pumphrey), 1126 : (C. J. Pennycuik), 1126
- Sundaram, R. (Krishnan, Sir K. S., and) : Radiative Transfer of Energy in the Core of a Heated Tube, 483
- Super-Cell Structure of Semiconductors (Dr. B. R. Pamplin), 136
- Superficial Microbial Colonies : An Improved Method for photographing (Prof. G. Nogrady), 602
- Supersonic Speed : Some Physical Problems in Travelling at (Dr. F. P. Bowden), 454
- Supplies (Water), for Small Communities, review by Prof. W. G. V. Balchin, 825
- Supply of Electricity : Research into the (Arthur Palmer), 366
- Supply (Water), for Rural Areas and Small Communities (Edmund G. Wagner and J. N. Lanoux), review by Prof. W. G. V. Balchin, 825
- Surface of a Parasite and the Haemocytic Reaction of its Host (Dr. George Salt), 162
- Surface of the Small Intestine : Influence of the, on Enzymatic Hydrolysis of Starch by Enzymes (Dr. A. Ugolev), 588
- Surface (Liquid), and a Needle Height-Gauge : Electrostatic Attraction between a (A. T. J. Hayward), 927
- Surface Fatigue (Rolling) : Hydrogen Diffusion in Water-accelerated (Dr. L. Grunberg, D. T. Jameson, D. Scott and R. A. Lloyd), 1182
- Surface Features (Lunar) : Origin and Nature of (Dr. J. J. Gilvarry), 886
- Surface Renewal and Molecular Diffusion in Interphase Mass Transfer (N. G. Maroudas and Dr. H. Sawistowski), 1186
- Surface-active Agents : Inhibition of Ehrlich Ascites Tumour Growth by (Prof. M. E. Hodes, Aaron K. Warren and Dr. Catherine Gardella Palmer), 157
- Surfaces (Sliding) : Motion of Molecules in Very Thin Films between (Dr. B. S. Thornton), 802
- Surgeons of England, Royal College of : Grant from the Wellcome Trust to Prof. R. Woolmer, for special research apparatus, 454
- Lister Medal awarded to Prof. W. G. Penfield, 984
- Surgery : Metals in, review by Dr. E. G. C. Clarke, 818
- Surgery (Bone and Joint) : Metals and Engineering in (Prof. Charles Orville Bechtol, Prof. Albert Barnett Ferguson and Prof. Patrick Gowans Laing), review by Dr. E. G. C. Clarke, 818
- Surridge, R. G. : At the Annual Conference of the Library Association (Lack of Attention to Bibliography in Libraries in Britain), 374
- Survey of Information/Library Units in Industrial and Commercial Organizations (C. W. Hanson), 21
- Survey of Man-power Needs in Health Science for the United States (Federation of American Societies for Experimental Biology), 1154
- Survey (Haemoglobin), among the Sherpas : *Thalassemia* in a Tibetan discovered during a (F. S. Jackson, Dr. H. Lehmann and Dr. A. Sharih), 1121
- Survey (Soil), in the West Indies (Prof. L. Dudley Stamp), 109
- Surveys : Soil and Land-Use (Regional Research Centre of the British Caribbean at the Imperial College of Tropical Agriculture), Monographs 4-10, 109

- Survival - Education for (Report on the Ninth Annual Conference of the East Midlands Group of the British Association for Commercial and Industrial Education), 257, 276
- Survival in the Cold, review by Dr. S. T. Cowan, 6
- Survival (Prolonged), of Human Sperm in Chemically Defined Media at Room Temperatures (Prof. Charles Norman, Erwin Goldberg, I. D. Porterfield and C. E. Johnson), 760, *erratum*, 899
- Survival (Virus), as a Seasonal Factor in Influenza and Poliomyelitis (J. H. Hemmes, Prof. K. C. Winkler and S. M. Kool), 430

- University of Birmingham : Retirement of Prof. H. P. Gilding from the chair of physiology, 103
- Appointment of Dr. Ian E. Bush to the chair of physiology, 103
- Harry H. Payne, Ltd., and the Harry Payne Trust to make further payments of £1,250 per annum and £1,000 per annum, respectively, to the Harry Payne Fund for a period of seven years, 279
- Appointment of Dr. G. M. Bennisson as lecturer in geology, 279, 539
- Appointment of Dr. T. S. M. MacLean as lecturer in electrical engineering, 279, 539
- Appointment of Dr. D. A. Wilkins as lecturer in botany, 279, 539
- Grant of £10,000 from the Wellcome Trust, for equipment to investigate the nature and functions of the proteins of brain and muscle, 454
- Establishment by the Medical Research Council of the Unit for Research on the Chemical Pathology of Mental Disorders, in the Department of Physiology, 454
- Appointment of Dr. P. Swinbank, C. P. Van Zyl and Dr. J. D. Dowell as lecturers in physics, 539
- Appointment of Dr. F. J. Emery as lecturer in mathematical physics, 539
- Appointment of Dr. E. F. Stack-Forsyth as lecturer in electrical engineering, 539
- Appointment of K. Foster as lecturer in mechanical engineering, 539
- Appointment of Dr. G. W. Rowe as lecturer in industrial metallurgy, 539
- Appointment of Dr. J. M. Webber as lecturer in chemistry, 539
- Appointment of B. W. Petley to a Fellowship in physics, 539
- Appointment of H. R. Shaylor as Staff Fellow in nuclear physics, 539
- Appointment of T. W. Preist and T. F. Tuan to Fellowships in mathematical physics, 539
- Appointment of B. Cockayne and Dr. N. Passall to Fellowships in physical metallurgy, 539
- Appointment of D. J. White to a Fellowship in engineering production, 539
- Appointment of D. G. Parsons as S. C. Johnson Research Fellow in the Department of Chemistry, 539
- Appointment of Dr. C. F. Wells as lecturer in chemistry, 784
- Appointment of Dr. F. Bakhtar as lecturer in mechanical engineering, 784
- Appointment of Dr. J. L. Jinks as honorary lecturer in the Department of Genetics, 784
- Appointment of G. Lines and P. Johnson to Research Associateships and Fellowships in medical biochemistry and pharmacology, 784
- Appointment of R. H. Hollier as Tube Investments Senior Research Fellow in the Department of Engineering Production, 784
- Appointment of G. R. Izak as lecturer in nuclear physics, 784
- Acceptance of an offer by Joseph Lucas, Ltd., to second to the University each year an American professor, to hold a Joseph Lucas visiting professorship in the Department of Engineering Production, 784
- University of Brazil : An honorary doctorate awarded to Dr. Detlev Bronk, 1156
- University of Bristol : Grant from the Wellcome Trust to Prof. H. Heller, for special research apparatus, 454
- University of California : Symposium on Control of the Mind, 193
- Publications in Geological Sciences, Vol. 37, No. 1, Fossil Mammalia from the Early Wasatchian Four Mile Fauna—Eocene of Northwest Colorado (Dr. M. C. McKenna), 200
- University of Cambridge : Physical Chemistry Summer School on Fast Reactions, 899
- Hand-List of Darwin's Original Papers in the University Library (R. V. C. Bailey and J. S. Gosse), 1154
- University of Cape Town : Appointment of Dr. J. M. Winterbottom as director of the Percy Fitzpatrick Institute of African Ornithology, 193
- University of Delhi : Appointment of Prof. B. R. Seshachar as professor of zoology, 707
- University of Dublin : Grant of £16,000 from the Wellcome Trust to Trinity College, to construct and equip an experimental surgery unit and an animal house, 454
- University of Edinburgh : Appointment of B. I. Davies as lecturer in bacteriology, 539
- Appointment of Dr. P. C. Jocelyn as senior lecturer in biochemistry, 539
- Appointment of Dr. L. G. Plackett as lecturer in biochemistry, 539
- Appointment of M. Jacobson as lecturer in physiology, 539
- Appointment of Dr. A. L. Bartlet as lecturer in veterinary pharmacology, 539
- Appointment of Dr. G. M. Carstairs to the chair of psychological medicine, 984
- Title of Research Fellow in the Department of Animal Genetics conferred on Dr. J. L. Sirlin, 988
- Appointment of D. M. Weil as lecturer in the Department of Bacteriology, 988
- Appointment of Dr. R. G. S. Leask as lecturer in the Department of Clinical Chemistry, 988
- Appointment of W. E. J. Farvis to the newly established chair of electrical engineering, 1072
- University of Glasgow : Grant from the Wellcome Trust to Prof. J. W. Howie, for special research apparatus, 454
- Appointment of Dr. J. H. Renwick as senior lecturer in human genetics, 988
- Appointment of R. W. P. Drever, W. Jack and E. W. Laing as lecturers in experimental and theoretical physics, 988
- Appointment of I. M. Hoodless and W. Parker as lecturers in chemistry, 988
- Appointment of J. S. Keates as lecturer in geography, 988
- Appointment of D. J. Simms as lecturer in mathematics, 988
- Appointment of G. L. le Bouvier to a Research Fellowship in genetics, 988
- Appointment of I. Hughes and D. A. R. Wallace to Research Fellowships in mathematics, 988
- Appointment of A. L. Porte as an I.C.I. Fellow in chemistry, 988
- Second Fleck-Lecture (Dr. John Paul), 988
- University of Guayaquil (Unesco Science Co-operation Office for Latin America and the) : Latin-American Symposium on Migration of Marine Organisms, 635
- University of Hong Kong : Appointment of Dr. W. D. Chesterman to the chair of physics, 781
- University of Hull : Appointment of Dr. D. W. G. Ballentyne as lecturer in physics, 539
- Appointment of Dr. J. Friend as lecturer in botany, 539
- Appointment of S. C. Kapoor as lecturer in philosophy, 539
- Appointment of Dr. P. Bruck and Dr. A. Richmond to Research Fellowships in chemistry, 539
- University of Leeds : Retirement of Prof. J. T. Whetton from the chair of mining, 536
- Appointment of Dr. H. J. King to the chair of mining, 537
- Appointment of P. Kelly as lecturer in metallurgy, 539
- Appointment of C. Mack as lecturer in textile engineering, 539
- Appointment of J. R. Proud as lecturer in agriculture, 539
- Appointment of Dr. D. F. Horler to a Research Fellowship in the Department of Leather Industries, 539
- Appointment of Dr. W. E. Seeds to a Research Fellowship in the Department of Biomolecular Structure, 539
- Title of emeritus professor of surgery conferred on Prof. P. J. Moir, 539
- Title of emeritus professor of zoology conferred on Prof. E. A. Spaul, 539
- Title of emeritus professor of mining conferred on Prof. J. T. Whetton, 539
- Appointment of Dr. H. M. N. H. Irving to the chair of Inorganic and structural chemistry, 784, 984
- University of Liverpool : Retirement of Dr. A. T. Doodson from the directorship of Liverpool Observatory and Tidal Institute, 625
- To be the sole responsibility for the Liverpool Observatory and Tidal Institute, 709

- University of London: Retirement of Prof. Wilson Smith from the chair of bacteriology at University College Hospital Medical School, 20
- Appointment of Dr. G. Belyavin to the chair of bacteriology at University College Hospital Medical School, 20
- Appointment of Dr. J. S. Rowlinson to the University chair of chemical technology at the Imperial College of Science and Technology, 24, 189
- Appointment of Dr. R. J. Goldacre to the readership in cell physiology at the Institute of Cancer Research, Royal Cancer Hospital, 24
- Appointment of M. J. Way to the readership in applied entomology at the Imperial College of Science and Technology, 24
- Appointment of Dr. C. B. Downman to the Sophia Jex-Blake chair of physiology at the Royal Free Hospital School of Medicine, 189
- Appointment of Dr. P. E. Polan to the Prince Philip chair of paediatric research at Guy's Hospital Medical School, 279
- Title of reader in haematology in the University (at Charing Cross Hospital Medical School) conferred on Dr. Sidney Shaw, 279
- Title of reader in bacteriology in the University (at Charing Cross Hospital Medical School) conferred on Dr. H. I. Winner, 279
- Grant of £50,000 from the Wellcome Trust to the Middlesex Hospital Medical School, for a suite of Wellcome Research Laboratories in the Pharmacology Department of the new Medical School building, 454
- Grant of £6,000 from the Wellcome Trust to the Postgraduate Medical School, to equip a cardiac catheterization research laboratory in the Department of Medicine, 454
- Grant of £5,500 from the Wellcome Trust to St. Mary's Hospital Medical School, for an analytical ultracentrifuge to investigate the structure of antigens and antibodies, 454
- Grant from the Wellcome Trust to H. A. Sissons (Institute of Orthopaedics), for special research apparatus, 454
- Grant from the Wellcome Trust to Prof. G. A. H. Buttle (School of Pharmacy), for special research apparatus, 454
- Appointment of Dr. B. J. Mason to the University chair of cloud physics at the Imperial College of Science and Technology, 539, 781
- Appointment of Dr. S. Cohen to the University readership in immunology at St. Mary's Hospital Medical School, 539
- Appointment of Dr. D. R. Laurence to the readership in pharmacology and therapeutics at University College and University College Hospital Medical School, 539
- Title of reader in tropical hygiene in the University (at the London School of Hygiene and Tropical Medicine) conferred on Dr. B. B. Waddy, 539
- Appointment of Prof. B. G. Neal to the University chair of applied science with special reference to engineering in the Imperial College of Science and Technology, 784, 896
- Code of Practice against Radiation Hazards (Imperial College of Science and Technology), third edition, 984
- Appointment of Dr. D. G. Evans to the University chair of bacteriology and immunology at the London School of Hygiene and Tropical Medicine, 988
- Appointment of Dr. J. D. N. Hill to the University chair of psychiatry at the Middlesex Hospital Medical School, 988
- The Imperial College of Science and Technology—New Physics Department (N. C. Barford), 989
- University of London Institute of Orthopaedics: Grant from the Wellcome Trust to H. A. Sissons, for special research apparatus, 454
- University of London School of Pharmacy: Grant from the Wellcome Trust to Prof. G. A. H. Buttle, for special research apparatus, 454
- University of Los Andes: Establishment of the Latin American Forestry Institute for Research and Training, 1153
- University of Malta (Royal): Appointment of Dr. O. L. Thomas to the chair of biology, 708
- University (Prefectural) of Mie: Report of the Faculty of Fisheries (1958-59), 897
- University of Nottingham: Appointment of Dr. G. B. Warburton to the chair of applied Mechanics, 624
- University (Ohio State): Symposium on Molecular Structure and Spectroscopy, 988
- University of Oxford: Grant of £16,300 from the Wellcome Trust, to construct an animal house for the use of workers in the Department of the regius professor of medicine, 454
- University of Oxford (Department of Education): Arts and Science Sides in the Sixth Form, 610
- University of Pennsylvania: Grant of £17,000 from the Wellcome Trust, to extend the support of the Wellcome associate professorship of research in anaesthesiology, 454
- University of Pennsylvania (American Carbon Committee and the): Fifth Conference on Carbon, 627
- University of Pittsburgh: To carry out a Survey of Man-power Needs in Health Science for the United States, 1154
- University (Technical), Prague (Faculty of Inorganic Chemistry), and others: Symposium on Co-ordination Chemistry, 715
- University (Purdue) (Department of Chemistry), and the United States Office of Naval Research: Symposium on Nitro Aliphatic Chemistry, 539
- University of Reading: Promotion of Dr. R. F. Glascock (National Institute for Research in Dairying) to Senior Principal Scientific Officer, 281
- The Cole Library of Zoology and Early Medicine, 1148
- University of Sheffield: Appointment of N. Moray as lecturer in psychology, 784
- Appointment of J. E. Enderby as lecturer in physics, 784
- Appointment of Dr. J. V. S. Mann to be I.C.I. Research Fellow in the Department of Fuel Technology and Chemical Engineering, 784
- University of Southampton: Grant from the Wellcome Trust to Dr. G. A. Kerkut, for special research apparatus, 454
- University of Sydney: The New Radio Astronomy Centre of the (Prof. H. Messell), 528
- Appointment of Dr. W. N. Christensen to the Peter Nicol Russell chair of electrical engineering, 784
- Appointment of Dr. L. C. Birch to the Challis chair of zoology, 784
- University of Texas M. D. Anderson Hospital and Tumor Institute: Symposium on the Molecular Basis of Neoplasia, 711
- University of Wales: Grant from the Wellcome Trust to Dr. K. S. Dodgson (University College of South Wales and Monmouthshire, Cardiff), for special research apparatus, 454
- University of Wisconsin: Critical Problems in the History of Science—Proceedings of the Institute for the History of Science, 1957 (edited by Marshall Clagett), review by Dorothea Waley Singer, 439
- University and other Students: Government Grants to, 897
- University Administration: Automatic Data-processing in, 710
- University College, London: Appointment of Dr. D. R. Laurence to the readership in pharmacology and therapeutics, 539
- University College of South Wales and Monmouthshire, Cardiff: Grant from the Wellcome Trust to Dr. K. S. Dodgson, for special research apparatus, 454
- University College Hospital Medical School, London: Retirement of Prof. Wilson Smith from the chair of bacteriology, 20
- Appointment of Dr. G. Belyavin to the chair of bacteriology, 20
- Appointment of Dr. D. R. Laurence to the readership in pharmacology and therapeutics, 539
- University Development: Some Problems of (Association of University Teachers), 789
- University Education: Student Grants for, I
- University Physics (Prof. F. C. Champion), revised edition, review by Prof. H. Lipson, 840
- University Teachers, Association of: Some Problems of University Development, 789
- Unturned: No Stone—an Almanac of North American Prehistory (Louis A. Brennan), review by Dr. G. H. S. Bushnell, 831

- Water : Decomposition of, by Light (Prof. H. Kallmann and M. Pope), 935
- Formation of Activated Hydrogen Peroxide by Irradiation of, with α -Rays (Dr. P. Alexander and Dr. D. Rosen), 574
- Radiation-induced Ionic Reactions—the Retardation of the Homopolymerizations of α -Methyl Styrene and β -Pinene by, 469
- Spectrum of Radiation Background under (Gordon K. Riel, John P. Doffis and Donald G. Simons), 266
- H₂O, HDO and D₂O (Molecules) : Ultra-violet Absorption Spectra of the (Prof. W. C. Price, P. V. Harris, Dr. G. H. Beaven and Dr. E. A. Johnson), 45
- Water (Free) : Production of, in the Mammalian Foetus (M. W. Stanier), 237
- Water (Fresh) : Productivity of the Sea and (British Association for the Advancement of Science, Section D (Zoology), Discussion on), 91
- Water (Rain-) : Contribution of, to the Nutrient Economy of Soil in Northern Nigeria (E. Jones), 432
- Water (Seepage) : Some Water-Mites from (T. Gledhill), 1074
- Water (Tritiated), in Fractional Distillation : Separation Factor of (P. Avinur and Dr. A. Nir), 652
- Water-Accelerated Rolling Surface Fatigue : Hydrogen Diffusion in (Dr. L. Grunberg, D. T. Jamieson, D. Scott and R. A. Lloyd), 1182
- Water-Balance Principle (Frog), and Arginine Vasotocin : Evidence for the Identity of Natriuretic, the (Prof. Wilbur H. Sawyer), *erratum*, 454
- Water-insoluble Trypsin Derivative and its Use as a Trypsin Column (Atara Bar-El and Prof. Ephraim Katchalski), 856
- Water-Mites from Seepage Water : Some (T. Gledhill), 1074
- Water Net, *Hydrodictyon* (Dr. M. A. Pocock), 545
- Water Phase of Gelatin Gels : Proton Magnetic Resonance of the (Erik Odeblad), 579

- Water Pollution Research Board : Report for 1959, 626
- Water-Stress : Effect of, on the Absorption of Soil Phosphorus by Wheat Plants (R. G. Fawcett and Dr. J. P. Quirk), 687
- Water Supplies : The Problem of Chromium in, 987
- Water Supplies for Small Communities, review by Prof. W. G. V. Balchin, 825
- Water Supply for Rural Areas and Small Communities (Edmund G. Wagner and J. N. Lanoix), review by Prof. W. G. V. Balchin, 825
- Water Treatment Handbook (compiled by R. Levial), second English edition, review, 837
- Water Waves : Generation of, by the Wind (Prof. Bruce L. Hicks), 1016
- Waterman, Talbot H. (edited by) : The Physiology of Crustacea, Vol. 1, Metabolism and Growth, review by Dr. J. Green, 810
- Waters (Australian) : The Concentration of Plankton Pigments in (Dr. G. F. Humphrey), 199
- Waters (Scottish) : A Pacific Salmon (*Oncorhynchus gorbuscha*) in (W. M. Shearer and Dr. E. Trewavas), 868
- Watkins, J. W. N. : At the fifth Annual Conference of the British Society for the Philosophy of Science (The Relation between Universality and Necessity), 458
- Watson, Dr. D. J. : Control of Plant Growth, review, 1060
- Watson, Dr. K. C., and Joubert, S. M. : Haemagglutination of Cells treated with Antibiotics, 505
- Watson, K. J. : Crystal Structures of 1-Chloro-2,4-Dinitrobenzene and 1-Bromo-2,4-Dinitrobenzene, 1102
- Watson, M. D. (Nicholls, Prof. R. W., and) : Shock Excitation of Solid Aromatic Hydrocarbons, 568
- Watson, Prof. W. H. : The Relativity of 'Meaning', 605
- Watt, W. : Promoted to Senior Principal Scientific Officer in the Scientific Civil Service, 281 ; work of, 281
- Watts, D. C. (Rabin, Dr. B. R., and) : A Theory of the Mechanism of Action of Creatine Phosphokinase, 1163
- Wave (Backward-) Oscillator : Operation of the (M. Y. Wong, Dr. G. D. Sims and Dr. I. M. Stephenson), 803
- Waves of Sand : Internal Waves and (A. H. Stride and M. J. Tucker), 933
- Waves (Hydrodynamic) : Evidence of Quasi-Perpendicular Propagation of, caused by Nuclear Explosions over Johnston Island (Prof. H. Maeda and T. Ondoh), 1018
- Waves (Internal), and Waves of Sand (A. H. Stride and M. J. Tucker), 933
- Waves (Plane) : Aberration of (Dr. E. F. Fahy), 396
- Waves (Submillimetre), by Harmonic Generation from Cold Cathode Arcs (Dr. K. D. Froome), 43
- Waves (Ultrasonic) : Velocity of, in Aqueous Solutions of Zinc Halides (S. V. Subrahmanyam), 570
- Waves (Water) : Generation of, by the Wind (Prof. Bruce L. Hicks), 1016
- Way, M. J. : Appointed to the readership in applied entomology at the Imperial College of Science and Technology, London, 24
- Weaning (Short-term) : Effects of, on the Acid-soluble Ribonucleotides of Rat Mammary Gland (Dr. D. Y. Wang), 1109
- Weather : Understanding (Sir Graham Sutton), review by M. Parry, 832
- Weather Research - Radar in, review by J. R. Probert-Jones, 526

STUDENT GRANTS FOR UNIVERSITY EDUCATION

THE report of the committee appointed in June 1958 under the chairmanship of Sir Colin Anderson "to consider the present system of awards from public funds to students attending first degree courses at universities and comparable courses at other institutions and to make recommendations" was published on June 2*. Eleven out of its sixteen members reported in favour of abolishing any means test for parents; but its key proposal is that all those ordinarily resident in Great Britain and admitted for the first time to first-degree courses in receipt of grants from the University Grants Committee should receive awards from public funds, provided, for universities in England and Wales, they had two passes at Advanced level in General Certificate of Education examinations or the equivalent; for Scottish universities they should have the statutory minimum entry qualification, that is, the 'attestation of fitness' of the Scottish Universities Entrance Board.

On July 28, the Minister of Education, Sir David Eccles, announced that, after consultation with the universities, local authorities and others concerned, the Secretary of State for Scotland and he accepted this recommendation. It was also their intention that the local authorities should continue to participate in the administration, but in view of the wide divergencies of view expressed by the public in regard to some of the Committee's recommendations, the Government needed more time to consider them. The Committee had specifically recommended that Parliament should make the Minister of Education and the Secretary of State for Scotland responsible for settling the detailed requirements, after rejecting proposals to simplify the present system either by making the universities, colleges and other institutions of higher education responsible for administering grants to students as agents of the Government, or by entrusting the award of all grants to an *ad hoc* national grants board, financed by public funds and enjoying some autonomy. The Anderson Committee recommended indeed that a Standing Advisory Committee should be appointed to advise the Ministers on decisions of policy and on problems arising in the day-to-day administration of the awards system; but while the Committee discusses in this report in some detail the advantages and drawbacks of local authorities as award-making bodies, it gives no clear lead as to the course to be followed. If the Ministry of Education and the Scottish Education Department do not assume entirely the detailed executive functions of award-making, it is suggested that these functions should be discharged by the two Depart-

ments but with the local authorities acting as their agents for some functions, or alternatively, by the local authorities, under rules drawn up by the two Ministers, subject to the students having a right of appeal to one or other of the Ministers.

From Sir David Eccles's statement it would appear that the Government intends to adopt something on the lines of the second of these three courses, possibly because it offers the best prospect of securing agreement in a field where opinions differ widely and are frequently strongly held. The Committee itself comments on the contrast between the community of interest and purpose among its witnesses and the wide diversity of their answers to the Committee's key questions. It was surprised to find how wide a difference of opinion existed, even within some well-defined groups, about the steps which should be taken to improve the present system and, except in minor matters, it was unable to detect any consensus of professional or public opinion on how to solve any of the main problems.

This is reflected to some extent in the report itself, though not, happily, in an admirable second chapter, which sets forth some general principles which should form the foundation of any system of granting awards from public funds. For this chapter alone and for the key recommendation already noted, as well as for useful but subsidiary proposals for simplification, the report is an important and valuable step which may yet lead to an agreement on major points of policy still at issue. It is a useful contribution to lucid thinking about a problem that has far-reaching implications, and not [its least important feature is the way in which the reasons responsible for divergence of views among [its own members on the question of the parental contribution are detailed.

First, the Committee is convinced that, while Britain urgently needs the greatest possible number of highly educated men and women, it should not depart from the ancient and sound tradition that young men and women go to a university to become all-round citizens and not merely to learn a special skill. Likewise, the Committee believes that no distinction should be drawn between men and women students: in the national interest all potential talent should be given its chance to develop. Full-time paid employment is not the only means of enriching the national life, and a sustained increase in the number of highly educated mothers, as well as fathers, would benefit the nation to an extent that is not yet generally appreciated.

The Committee recognizes that its proposals can scarcely avoid having an effect on both schools and universities, though this is not intended; and it thinks that the greater responsibility should properly rest on the universities and colleges. Nevertheless, it

* Ministry of Education: Scottish Education Department. Grants to Students: Report of the Committee Appointed by the Minister of Education and the Secretary of State for Scotland in June 1958. Pp. xli+186. (Cmd. 1051.) (London: H.M. Stationery Office, 1960.) 6s. 6d. net.

is impressed with the need for uniformity in the treatment of applicants for awards, and the Standing Advisory Committee it proposes is intended to assist here and to deal with the practical and human problems that will inevitably present themselves. No feature of the report is more impressive than the way in which the Committee recognizes these human problems and seeks to dispel the anxiety which many students at present inevitably experience while waiting to hear whether they will receive the grant on which their ability to take up a university place depends. This is very notable in the comparatively minor recommendations contained in the final chapter of the report, which discusses various practical matters of importance to students and their parents.

Nor is this human interest one-sided. In commenting on the importance of interviews, the Committee expresses the hope that universities, in addition to making more uniform the present procedures and conditions of admission, will extend so far as possible the practice of interviewing candidates before acceptance. Quite apart from the function of interviews in helping to determine the choice between one border-line candidate and another, it believes that the influence of a properly conducted interview on the student himself is important. As the Committee rightly remarks, the student will in effect be applying for a grant of a large sum of public money, and it is unquestionably right that a positive effort should be made, in an interview, to remind the applicant that he or she is seeking the privilege of being backed by the community. Recognition that a university place is a privilege—although it has been earned—is too often overlooked, and if it were more generally remembered, as well as its implications, the criticism that many graduates look on a post as something which the community owes them, rather than as an opportunity to serve the community, might be less frequently heard.

This could be the more important if universities became in effect free for all as a result of the adoption of the majority recommendation to abolish the parental contribution. The Committee's observation, moreover, gains strength from the obvious liberality of the views of its members and their sympathetic understanding of the point of view of the student. The Committee is emphatic that students throughout Great Britain should have the freedom of choice of institution. Much of the value of higher education, it points out, lies in the contacts the student makes and the life he leads within the student community and outside the lecture room and the laboratory; and to get the full benefit, it is important that the student body should not be drawn from too narrow a field—it will gain richness from a wider field. Again, the Committee believes that it is important that students should be able to rely on a grant for the full normal period of the course on which they have embarked, and it specifically recommends that all awards should be so made, subject only to satisfactory progress and conduct and to appropriate measures to deal with arbitrary changes of courses

by indifferent students while taking care of reasonable changes, particularly at the end of the first year.

Of the selection for awards no more need be added than that the Committee is emphatic that the universities themselves are best fitted to select those who should receive a university education. It thinks that since effective selection by local education authorities is mainly confined to border-line candidates, the return, in terms of improved selection and of public money saved, is small, and the present arrangements impose an undue burden on the schools and their pupils. It also concludes that no second process of academic selection should be required for the main stream of entrants to first-degree and comparable courses.

The major issues on which the Committee was agreed may be briefly reviewed. It recommends in the first place that the method of expressing the maximum grant in terms of "payment of fees plus a standard sum for maintenance" should apply throughout Great Britain, and each standard figure should include the same amount for books, clothes and incidental expenses. It rejects firmly the suggestion that the grant for books should be in kind. The student should be treated as a responsible person and left free to spend the money granted according to his own circumstances and his judgment of his own needs. Further, it thinks it important that the student and his university teachers should be aware how much has been allowed in his grant for the purchase of books, and accordingly publication of this amount is recommended. It also recommends that a fixed sum for travelling expenses should be included in the standard figure of maintenance, and it endorses the principle of grouping universities and of including in the standard figure of maintenance for each group an amount for the maintenance of students living in colleges or halls of residence or in lodgings. Holders of awards should be covered for the payment of national insurance.

In all this detailed assessment of the needs of holders of awards, the Committee treats the student as a responsible person, and if its sensible recommendations are adopted, it is only reasonable to expect that this will be generally recognized by students themselves. The recommendations for grants for vacations and vacation courses are no less sensible, and are generous although clearly recognizing the public interest. They are based on five principles: that award-holders should receive standard grants for maintenance throughout the vacations; this grant should be calculated at the same rate as that for 'keep at home' during term-time; the grants should be paid before the vacations for which they are given; deductions from subsequent grants should be made for any vacation periods in which the holder has been in paid employment; the standard vacation grant for the final long vacation should be calculated to cover four weeks only, and should not be subject to any declaration about paid employment.

The miscellaneous recommendations stress the importance of dealing with all applications for awards

as quickly as possible. A pamphlet should be printed to provide a general guide to the awards system, and if university and comparable awards remain the responsibility of local authorities, it is essential that full information about the local arrangements is widely available in each area. When the student is notified of the amount of his grant, he should also be told the conditions attached to the award and given a statement of the way in which it will be administered. If parental contributions are retained, the parent should be notified both of the amount of the grant to the student and of the amount of the parent's contribution. The recommendations regarding payment of awards are also sensible and would eliminate the practice of withholding payments until a certificate of attendance has been obtained from the university or college authorities. Instead, subject to the agreement of the university or college authorities, cheques for ordinary grant payments should be made available to award-holders through the university or college office, on the lines now followed by the Ministry of Education for State scholars. In addition, the Committee recommends that all award-holders should be able, on application, to draw an advance payment of up to £30 before the start of their first term.

Collectively, these minor recommendations should not only simplify the present system and establish some uniformity of practice, but also remove some of the anomalies and grievances which have been a source of complaint and even hardship to students. Nor is the cost excessive. With the abolition of parental contributions, the net cost of which in 1958-59 is estimated at £5.5 million, the total increased cost arising from the proposals of the report is about £8.2 million, compared with £7.1 million if the modified parental contributions suggested as alternative are adopted. For a university population of 135,000, assuming the students from the United Kingdom following first-degree courses continue to form roughly the same proportion as in 1958-59, the cost to public funds is estimated at £22.9 million under the present system, £32.3 million with modified parental contribution and £33.8 million if the parents' contributions are abolished.

Financial considerations should thus not be of decisive importance in determining the abolition or retention of the parents' contribution, particularly in view of the general agreement that some modification is required; and the difference in opinion between the advocates of a more generous system and those who would abolish the parents' contribution does not turn on cost. The evidence submitted to the Committee indicated that, while none of the bodies giving evidence was entirely satisfied with the present system, the reforms suggested differed widely. Out of seventy organizations, forty recommended complete abolition of the parents' contribution and fifteen its abolition for approved fees while retaining it for maintenance. Moreover, it was apparent that differences of opinion existed within the organizations themselves, and the division of opinion on the

Anderson Committee itself thus reflects that existing in Britain generally.

Nevertheless, it is important to note that there was a considerable measure of agreement on the Anderson Committee. It was agreed, for example, that none of the half-measures suggested offers a satisfactory solution, and that a straight choice has to be made between relieving parents altogether or maintaining a system of assessment of parental income for awards purposes. Again, the Committee agreed that the abolition of parental contributions would be a fundamental change, and that an assessment of its probable effects is a matter of judgment. In the Committee, the difference of opinion lies in the assessment of those effects. The majority is firmly convinced that they would be beneficial, and the argument is cogently and convincingly presented. The minority sees a strong possibility of harm, and does not regard the difficulties of the present system as serious enough to warrant running the risks involved in abolition; but that case is far less convincingly argued. None the less, all are agreed that the demand for parental contribution must deter some well-qualified boys and girls from entering universities, that the present system imposes too heavy a burden on many parents and students, and that if parental contributions are retained they must be substantially reduced. There is also agreement that the level of contributions proposed in the report, which would, for example, relieve a married couple with one child from any contribution if their gross income is less than about £1,000, would largely remove the hardship on the middle-income parent on whom the present scale bears most heavily.

Having gone so far, the majority of the Committee would complete the process by abolishing the parental contribution altogether; believing that the higher the income below which no contribution is expected, the greater the number of families who get complete exemption and the smaller the actual yield both absolutely and in proportion to the cost and the administrative effort involved in collection. Secondly, and even more important, the smaller the number of families who are still required to make a contribution, the less the exaction of that contribution can be justified on grounds of general equity and the greater its resemblance to a discriminatory tax on a limited section of the community. If the level of contributions recommended in the report is adopted, about 60 per cent of all the present university and comparable awards would not be subject to parental contribution, and there is logic in the Committee's contention that a system of university awards should not superimpose what is in effect a second taxation system on some parents.

Whether or not the argument that abolition of the parents' contribution would provide a great stimulus to higher education is sound, the elimination of administrative complexities is undoubtedly an advantage, and it is clearly unjust and illogical to allow an awards system to penalize a small class of parents; not does the minority advance any convincing social or practical reasons for its retention. Prof. Brinley

Thomas, who also considers that the Committee does less than justice to the role of the State scholarship in the educational system of Britain in recommending that all types of State scholarship should be discontinued and suggesting that the State scholarship should be retained in a new form, with possibly a new name, dissents from his colleagues who wish to retain the parents' contribution in advocating at the same time the introduction of substantial sixth-form bursaries in the maintained schools. He regards public expenditure on ensuring that gifted boys and girls in the public sector are able to stay at school until the age for entry into the university as a first priority, and holds that to remove or reduce drastically the cost of university education for middle-class families while doing nothing to stop the leakage of talent among children at the age of fifteen in the lower-income groups would be an unwise and unjust use of public funds.

Prof. Brinley Thomas's note of reservation is much more cogently and convincingly argued than his colleagues' case for retaining the parental contribution; but nevertheless, he does not meet the real objection, namely, that to retain that contribution under present conditions is tantamount to differential taxation. It should be remembered, moreover, that the report proposes that parents should no longer be able to deduct child allowances from their taxable incomes in respect of children receiving grants. While it is perhaps understandable that the report should be somewhat hesitant in dealing with the financial aspect of the administration of grants as between the Government and the local authorities, the Committee leaves the Government in no doubt as to where the weaknesses of local authority administration lie and the need for some central direction in order to secure uniformity. That question must be settled by the Government before effect can be given to the rest of the report, and it is to be hoped that there will be no undue delay in reaching a firm decision and giving effect to some such simpler and fairer system of awards as the report outlines and removing injustices which were recognized as such by all its members.

UNIVERSITIES OF THE COMMONWEALTH

Commonwealth Universities Yearbook, 1960

Edited by J. F. Foster, assisted by T. Craig. Thirty-seventh edition. Pp. xxxi + 1509. (London: Association of Universities of the British Commonwealth, 1960.) 84s.; 13 dollars.

THE bulky appearance of this well-established Year-Book is an effective reminder of the extent of higher education in the Commonwealth. It was first launched in 1914, and, because of stable conditions in its first year of life, did not need revising each year.

Since then thirty-seven volumes have appeared, and, because of rapid changes, now needs to be re-issued in new dress each year.

When the Year-Book edition of twenty years ago was published, it included references to eighty separate university institutions and recorded a (full-time) population of less than a quarter of a million students. In the present volume 135 institutions are encompassed with a total student population of 1,115,000.

The 1960 Year-Book follows a year of remarkable progress in Commonwealth educational development made noteworthy by the Commonwealth Education Conference held at Oxford in July, 1959. One of the recommendations of the Conference was the launching of a scheme to award a thousand scholarships, mainly at the postgraduate level, tenable in the 'sponsoring' countries by students from the rest of the Commonwealth. A special appendix describes the working of the scheme.

Five new universities are included for the first time. These are Monash University in Australia, and Gorakhpur, Jabalpur, Marathwada and Vikram Universities in India; their inclusion is itself tribute to the way the Commonwealth countries are developing their professional man-power. One small item which will give much pleasure in Britain is that "the youngest member of the university family is the University College of Sussex at Brighton which was formally constituted in 1959 It is hoped that enough progress will have been made with academic buildings and the recruitment of staff for 200 students to be admitted in October, 1962".

The format of the book follows the pattern of earlier years, universities being grouped in countries, and each group is introduced by an essay describing in general terms the university system of the country and its general provision for higher education. For the first time the British section includes a table showing at which colleges of the University of London courses for a first degree are provided in fifty different subjects of study. This supplements a similar table for the universities of the United Kingdom as a whole which was warmly approved when it was introduced two years ago; it re-appears in the present edition.

One feature of the book which should bring legitimate pride to graduates from universities of the 'Mother Country' is that there are few faculties of universities in member countries which do not include some members of staff with British degrees. Before becoming overwhelmed with self-gratification, however, British graduates should study the interesting faculty developments in other Commonwealth universities and reflect whether or not development in Britain is still too hide-bound by tradition.

The value of this tremendous compilation is well brought out in Appendix 1. Without introduction or explanation it includes details of the Universities of the Republic of Ireland; it is encouraging to find a way of seeing that our Irish friends are not left out.

Other appendixes deal with university admission requirements, particulars of students from other countries who are not at present in British universities; details of British academic institutions abroad and of the Association of Universities of the British Commonwealth whose book this is. Could they now be persuaded to ask a research student to investigate the entrance examinations to all Commonwealth universities, the patterns (and costs) of administration, student admissions, rejections and achievements, and to issue a report? The overall view would be received with interest.

FIRST CENTURY ROMAN ARCHITECTURE

Roman Construction in Italy from Tiberius through the Flavians

By Marion Elizabeth Blake. Carnegie Institution of Washington. Publication No. 616. Pp. xvii+195+13 plates. (Washington, D.C.: Carnegie Institution of Washington, 1959) Paper 8.25 dollars; cloth 9 dollars.

IN 1957, Dr. Marion Blake published her "Ancient Roman Construction in Italy from the Prehistoric Period to Augustus", a chronological study of the methods and materials employed by the earliest Roman builders which has proved of great value to scholars. Now she continues her researches through the first century A.D. to the end of the Flavian period, incorporating into them, as before, many of the copious notes and photographs left by the late Dr. Esther Van Deman for a work of this kind. The extensive bibliography shows, however, how these have been supplemented by the work of other scholars, while the illustrations include excellent photographs by Prof. Lugli and Dr. Ernest Nash.

About half the length of its predecessor, the new volume begins with a brief introduction describing the building materials in use during the time of Augustus and the types of evidence valuable for chronology. After this the detailed examination of the evidence begins in Chapter 2, covering the Julio-Claudian Epoch from Tiberius's accession in A.D. 14 to Nero's death in A.D. 68. Tiberius seems to have adopted no innovations, apart from an increased use of brick-faced concrete, and Claudius built comparatively little in Rome. But Nero was anxious to beautify and enliven his city, and in the early years of his reign new baths and an amphitheatre arose as well as a palace, the Domus Transitoria. The great fire of A.D. 64 gave him an opportunity for town-planning which he used wisely, replacing the narrow, crooked lanes with wider streets and open spaces. Less timber was used for building and the employment of Gabine stone and peperino was encouraged as these materials were believed to be more resistant to fire. Plans were made for the great Domus Aurea which replaced the Domus Transitoria, but the new palace was never completed, and many interesting constructional details are revealed by its unfinished state. The walls show the first use of concrete faced with the triangular bricks made by cutting square tiles diagonally in half, and several new developments in vaulting are also noted. Roman private houses and tombs of this period are also briefly described, and some consideration is given to building in other parts of Italy, notably at Ostia and at Pompeii, where the earthquake of A.D. 62 made extensive reconstruction necessary.

The third chapter takes us from the Civil War of A.D. 69 to Domitian's death in A.D. 96. Vespasian, the first of the Flavian emperors, continued Nero's policy of reconstruction. He also initiated the building of the Colosseum, work which was carried on by his sons, Titus and Domitian. Dr. Blake's account of it is full of details of human as well as of structural interest; for example, the use of awnings to shade the spectators from the sun, and the various barriers and other measures needed to protect them from the wild beasts. Titus's brief reign is chiefly noteworthy for another disastrous fire in A.D. 80. As a result of it his successor, Domitian, was faced with problems

similar to those which confronted Nero and he also seized the chance to add, enlarge or elaborate. Temples, baths and fora, as well as the great palace on the Palatine hill, were all under construction during his reign. The chapter concludes with an interesting description of buildings on the imperial estates, various engineering works and public monuments in other parts of Italy, and the latest developments at Pompeii and Herculaneum prior to Vesuvius's eruption.

The final summary includes a brief résumé of building methods, and shows us how the development of a nearly perfect concrete left architects free to experiment with ground-plans of increasing elaboration. Not all the problems of weight and stress, however, had yet been solved, and consequently much of Domitian's vaulting was to need reinforcement in Hadrianic times. This carries us beyond the limits of the present book, and we look forward to the next volume in the series which, Dr. Blake promises us, will carry her researches to the time of Constantinian.

JOAN LIVERSIDGE

THE MECHANISM OF ADAPTIVE BEHAVIOUR

Design for a Brain

The Origin of Adaptive Behaviour. By W. Ross Ashby. Second edition, revised. Pp. ix+286. (London: Chapman and Hall, Ltd., 1960.) 42s. net.

AT one time it was not generally thought that learning could be regarded as a mechanical process. The view that it could is now widely held. This is due partly, if not largely, to Dr. Ashby's writings over the past twenty years. A major work of his, "Design for a Brain", now appears in its second edition. This is virtually a new book. Its object is to analyse the character of the activity of the brain, and learning in particular, in mechanistic terms. To drive home this approach an analogue computing device, the homeostat, has been so constructed as to exhibit purposeful, adaptive behaviour. The description and discussion of this device remains one of the central features of the book.

In broader terms, "Design for a Brain" is devoted to the consideration of goal-seeking mechanisms that change continuously. Mechanisms using discrete-step operations are easier to analyse, but continuously changing mechanisms are more readily comparable with organisms. Dr. Ashby is a creative thinker and a rigorous one. He defines precisely all the terms he uses. He deals with dynamic systems, that is, with sets of variables selected from vast numbers of variables that constitute machines. The systems considered are those that are stable and that show purposeful behaviour. The stability in a system, brought about by feedback, characterizes only certain combinations of the parts of the system. It is contended that adaptive behaviour of a system, or learning, is mediated by two feedback loops, one forming a close link between sensory and motor channels and another "working intermittently and at a much slower order of speed". Such a system is called ultra-stable, and the behaviour of the homeostat exhibits ultra-stability.

The action of the brain appears to be in principle like that of an ultra-stable system, but, of course, it is much more refined than anything so far designed.

Chapters 1-9 of the book are concerned with the basic problem of the mechanism of goal-seeking, adaptive behaviour, while Chapters 10-18 give consideration to the refinements of such a mechanism. One of them is a method for coping in an efficient manner with recurrent disturbances in the environment. Again, the homeostat is so constructed that every unit interacts with every other unit. It is shown that this makes for slowness of adaptation. It is known that in the brain not all units are interconnected. The book considers designs in which units are not fully joined, and where success at learning that is partial is not disregarded. This brings us a little nearer to biological reality which the machine design attempts to meet. Another step towards this end that is being considered is poly-stability; a poly-stable system "is any system whose parts have many equilibria and that has been formed by taking parts at random and joining them at random".

Dr. Ashby is knowledgeable in many fields. The reader cannot fail to be impressed by the precision of his exposition. Even so, many will retain a sense of doubt. Put briefly, the doubt is as to whether the approach represented by "Design for a Brain" is the right one towards a better understanding of the functioning of the brain. In striving towards this aim there is, of course, no substitute for experimental studies in physiology and psychology. The cybernetic approach is likely, however, to be of some help to many of those who are engaged in experimental work.

W. SLUCKIN

SURVIVAL IN THE COLD

Recent Research in Freezing and Drying

Edited by Dr. A. S. Parkes and Dr. Audrey U. Smith. Pp. vii+320. (Oxford: Blackwell Scientific Publications; Springfield, Ill.: Charles C. Thomas, 1960.) 63s. net.

IN 1951 the first international symposium on freezing and drying created a great deal of interest and the Institute of Biology, which organized it, decided that so many advances had been made that a second symposium was justified in 1958. Unfortunately, it has taken two years for publication of the papers presented so that the volume is already out of date in many of the subjects with which it deals. At the first symposium Fry had shown that the addition of glucose decreased the lethal effect of freeze-drying for micro-organisms, and many of the papers read in 1958 described work or theories to explain the role of adjuvants such as glucose, sucrose and glutamate. The effects varied with the method of freeze-drying used; Greaves showed that a mixture of 5 per cent dextran and 5 per cent sodium glutamate was excellent for bacteria that were pre-frozen but was not suitable for the spin-freeze method of drying; for this method a mixture of 5 per cent bovine albumin and 5 per cent sodium glutamate was satisfactory. Obayashi reported that for *BCG* vaccine glutamic acid alone gave better survival-rates than glutamic acid plus sugar. On the other hand, Muggleton used a mixture of dextran, sucrose and glutamate for his *BCG* vaccine. W. J. Scott believed that certain essential metabolites of living cells may be toxic to dried cells. This hypothesis is controversial, but Scott's finding that survival depends on the water activity of the dried product will find more general acceptance. G. R. Scott and Rampton sought

guidance on the influence of size of batches in the preparation of virus vaccine. Their experiments suggested that the difference in antigenicity between different batches was much less than Daubney had postulated in 1951, and asked if they had misinterpreted their results.

An important part of the symposium, and so of the book, dealt with the freezing and drying of tissues, and here the greater advances were recorded. The use of glycerol to prevent ice crystal formation has done much to make the freezing of cells a safe procedure but, of course, glycerinated material cannot be dried. Bone, skin, arteries and corneas have all been freeze-dried; but, as Parkes says, the tissue cells seldom survive, and the material only forms a scaffolding on which new tissue can form. In the cornea freeze-drying modifies the protein constituents, and the antigenicity of the material is so reduced that it is possible to use tissue from another animal species.

Several papers dealt with the theoretical aspects of freezing and drying and these have a special interest for the biophysicist. In general, the papers are printed as they were delivered, and, as few make attractive reading, it is a pity that the editing was not more strict.

S. T. COWAN

MATHEMATICAL METHODS IN ECONOMICS

Studies in Linear and Non-Linear Programming
By Prof. Kenneth J. Arrow, Prof. L. Hurwicz and Hirofumi Uzawa. With contributions by Hollis B. Chenery, Selmer M. Johnson, Samuel Karlin, Thomas Marschak and Robert M. Solow. (Stanford Mathematical Studies in the Social Sciences, Vol. 2.) Pp. ix+230. (Stanford, Calif.: Stanford University Press; London: Oxford University Press, 1958.) 60s. net.

THIS book is the second in the series, Stanford Mathematical Studies in the Social Sciences. It is a collection of research papers, and most of the results were obtained during 1955-58. It is divided into three parts, after an introductory chapter which explains and summarizes the contents of the various papers.

The first part is purely mathematical and deals with existence theorems, including the Kuhn-Tucker theorem on concave programming. There is a paper by Hurwicz on programming in linear spaces, and this includes an account of linear topological spaces and their properties. This account is of an introductory nature and will help considerably the reader who is not already familiar with the field.

The second part is concerned with the gradient method, so called because the gradient of a certain vector figures prominently in it. The idea is to solve a certain set of differential equations by using the finite difference approximations. The gradient method is available for non-linear programming problems, but for a linear problem it is not suitable since it gives rise to an oscillatory rather than a convergent path.

The third part deals with methods for solving certain particular problems, linear or non-linear. One problem concerns price speculation, where an individual may buy or sell a commodity, but is not allowed to borrow. If the costs are those for holding a stock

of the commodity the problem is linear; but if the costs are brokerage fees proportional to the amount bought or sold the problem is non-linear. Optimal operating policies are determined in each case. Another problem deals with the allocation of n tasks to m machines, where the machines are ordered in terms of increasing capability and the tasks in order of increasing difficulty. A third problem—directly in the field of inter-industry economics—is solved by a method which was originally applied to the problem of resource allocation in under-developed countries.

Mathematics has by now invaded in force the social sciences. The vigour with which various classes of problems in economics, for example, are being attacked mathematically is quite surprising. This situation implies an increasing divergence between what one might call the verbal or linguistic economist and the econometrician, who deals, so far as possible, with measurable concepts. The book under review is certainly meant for the latter—in fact it will probably only be understood by the mathematician interested in economics rather than the economist who would like to understand the workings of mathematics within his subject.

L. S. GODDARD

MANAGEMENT IN THE UNITED STATES AND THE U.S.S.R.

The Red Executive

A Study of the Organization Man in Russian Industry. By Dr. David Granick. Pp. 334. (London: Macmillan and Co., Ltd., 1960.) 21s. net.

AN amalgam of wide reading, many personal discussions and actual visits to a variety of industries inside the U.S.S.R. and the United States has enabled Dr. D. Granick of the University of Wisconsin to provide a great deal of comparative information about Russian and American management which hitherto has been subject to little more than speculation.

During his investigations Granick set out to determine the educational background of the managers, the pressures and incentives which govern their lives, the tasks before them and how the factories and social environment of the U.S.S.R. differ from those in the United States. For the British student, at least, the book is most satisfying and worthy of recommendation to many readers. The most striking of the findings are those which show that the similarities between the Russian and American management greatly outnumber the differences and, indeed, link them more closely than American and British managers.

The main differences stem from the nature of each country's economy. In the U.S.S.R. the marketing manager does not exist; everything produced can be sold. Salesmanship, advertising and product design to meet competition and make last year's model obsolete, which are major American pastimes, do not exist in the U.S.S.R. Their problem is the getting and allocation of raw material, and the American purchasing officer is replaced by a procurement official.

A major difference might appear to be the place of the trade unions. Whereas in the United States the unions are reputed for their ability to drive hard

bargains and, sometimes, disrupt production, in the U.S.S.R. the trade unions are imagined to be apostles of productivity and essential props for management. This may well be, but those familiar with the politically backed works commune would support Granick's statement that the American manager has little cause for grumbling compared with the Russian. A surprising difference is that the Russian manager is much more prepared to try out new ideas than his American counterpart. Granick believes that this may spring from the much more "theoretic" nature of the Russian training.

Among the many similarities of the Russian and American managers, the most striking (and from the British point of view the most challenging) lies in their educational backgrounds. In the U.S.S.R. the majority of managers get full-time education up to university level; in the United States little more than half are college-trained. In the U.S.S.R. the majority have engineering degrees; in the United States almost half the college-trained managers have general arts degrees. The American preoccupation for the "rounded" man is bound up with the fact that students are free to choose courses for themselves. This is also true of the U.S.S.R., but the courses made available are circumscribed by the needs of the economy.

The American graduate business training schools are largely missing in the U.S.S.R., which professedly believes in the value of manual work in introducing graduates to industry. The differences are not so great, however, because the Russian engineering graduates take a postgraduate diploma which necessitates involvement in an industrial organization. Another point of similarity is that, although the position is hardening in the United States, in both countries the way to the top is still wide open to the boy of ability and application.

Many other matters emerge to make this book of absorbing interest. Russian academic authorities, for example, appear to be as hazy about Russian management practice as most American university lecturers are about what goes on in their business training schools. The echo from Britain would also resound to complaints from research workers from both sides of the Iron Curtain about the difficulties they meet in obtaining permission to study factory administration in any kind of depth.

In both countries students are encouraged to work in industry as part of their educational (*sic*) development. One large American university has about one-seventh of its better-off full-time students doing forty-hour-a-week jobs. In the U.S.S.R., as in Britain, the student is expected to study full-time during university term. Before graduating to the managerial level, however, the Russian spends a considerable period as foreman or assistant. The attitude of some British university teachers to vacation work for students may need reconsideration.

Granick also deals with the size of industry in both countries, the inverse operation of Parkinson's Law in the U.S.S.R. over the past twenty years (this supports those who believe it to be based on false premises), the lack of definition of the foreman's job in the United States, U.S.S.R., and Britain, and enough related matters to make his book worth a place in libraries in many countries. He should now perform a service to British management by preparing a second volume describing the observations he has made during his year as a Fulbright Fellow in Great Britain.

T. H. HAWKINS

The Road to Man

By Herbert Wendt. Translated by Helen Sebba. Pp. 253+31 plates. (London: Lutterworth Press, 1960.) 30s. net.

IN his preface the author of this work confesses "The Road to Man" is therefore not just a sober, factual account of the animal world, but a kind of novel of the animal world, a novel with many chapters—which are only superficially disjointed". Depending on one's estimate of superficiality, this is an acceptable description of the book. In the course of twenty-nine brief chapters reference is made to virtually the whole of the animal kingdom. It follows that scant justice is accorded to most aspects of the subject, and the general reader, for whom the book is intended, will close it with some dissatisfaction at having been brought to innumerable doorways and then led hastily away in order to complete his tour before closing time. Mr. Wendt's objective has been to demonstrate man as one among many animals, and not, as many would like to think him, the central figure about which the rest of Nature revolves. It cannot be said that he has successfully achieved this admirable end, although certainly he has demonstrated an enormous diversity of natural phenomena. But the pattern inherent in his sub-title, "An Informal History of Evolution", is sacrificed to a disjointed series of examinations of individual threads in the weave.

Inevitably, with so much ground to cover, the author has taken many short cuts to what he believes to be the truth, and many of these are tolerable approximations to probability. But it is impossible to pass unchallenged such statements as "Protoplasm which has the same chemical structure as that of the sea at the time when life is believed to have evolved" (p. 22), or "A lot still had to be accomplished before the lampreys became real vertebrates" (p. 64). Nor can one accept the assumption that "the mature eel being totally oriented to seaweed and deep sea . . ." is thereby constrained to migrate to the Sargasso Sea in order to breed; while the description of the actively carnivorous habits of sea urchins can only be ascribed to the author's aforementioned fictional approach to his subject. The book is embellished with a number of excellent photographs, rather more randomly selected than is the text. A word must be added in praise of the translation, the style of which is excellent.

L. A. HARVEY

Studies on Agar Gel Electrophoresis

Techniques—Applications. By R. J. Wieme. (University of Ghent: Department of Internal Medicine.) Pp. 531. (Brussels: Arsacia Uitgaven, N.V., 1959.) 680 Belgian francs.

THE beautiful technique of immuno electrophoresis introduced by Grabar and his associates gave great encouragement to the choice of agar gel as a supporting medium in zone electrophoresis. It has a number of advantageous features such as good resolving power for proteins, adaptability for very small scale work, and its ability to be converted to a thin transparent film after electrophoresis and staining makes it suitable for photometric scanning. These and other features are discussed in much detail by Dr. Wieme in his monograph. The author describes his various modifications of carrying out the electrophoretic run on microscope slides coated with agar, and of interest is an ultra-microprocedure whereby as little as 0.03 μ l. of serum or 2 mgm. of

tissue may be analysed. Applications, mainly of one particular micro technique to studies of constituents of normal human sera and of animal tissue enzymes, are described, and thereafter clinical studies of sera in some fields of wide interest, namely, plasmocytoma and primary macroglobulinaemia, modification of γ -globulin in disease and examination of lactate dehydrogenase in disease. All the sections include a thorough survey of the work of others and a good coverage of the literature on the various subjects discussed.

This monograph gives a highly detailed exposition of practical and theoretical aspects and is therefore of value to those interested in agar-gel electrophoresis. Unfortunately, it is written as a thesis and therefore not entirely suitable for general reading. It could form the basis of a very useful book of wide appeal if the subject-matter were better arranged, unnecessary details cut out and the English improved. (Some of the phrases, being literal translations of Flemish idiomatic expressions, are very quaint, and would delight the heart of Paul Jennings.) There is a great deal of useful information in this work, and so it would be a pity to leave it in its present form and not attempt to make it more presentable and more reasonably priced.

R. CONSDEN

The Indian Ephemeris and Nautical Almanac for the Year 1961

Pp. xxvi+448. (Delhi: Manager of Publications, 1960.) Rs. 12.50 nP.; 10s. 6d.

THIS volume, the fourth annual issue of the "Indian Ephemeris", plays an important part in the development of modern astronomy in India. It is a worthy tribute to the enthusiasm and persistence of the late Prof. M. N. Saha, to whom the original proposal and a large part of the preliminary organization and planning were due.

The initial impetus for the introduction of a separate "Ephemeris" arose from the necessity to reform and unify the many different calendrical systems in use in India. It is therefore not surprising that no fewer than 48 pages are devoted to the Indian Calendar, giving full details of the Reformed Calendar of India.

In other respects the ephemeris follows very closely the models adopted by the other national ephemerides. The fundamental calculations have for long been shared between the ephemeris offices of France, Germany, Spain, the United Kingdom, the United States, and the U.S.S.R.; and these have been made readily available for the preparation of this volume. The work of preparation has thus largely been concerned with compilation, presentation and printing: these have been done excellently under the competent guidance and supervision of Sri N. C. Lahiri. But the ephemeris of the Moon at ephemeris transit, and the special tables of sunrise, sunset, moonrise, and moonset for India have been calculated specially.

The low standard of practical astronomical knowledge in India, coupled with the prevalence of astrology, was one of the main reasons for the inauguration of a new national ephemeris at the time when, in other countries, there was a strong tendency towards unification. The introduction of the "Indian Ephemeris" has already started to inspire serious astronomical work in India; in general competence and in attention to detail, of both content and presentation, no better standard for that work could have been set up.

D. H. SADLER

WORLD FOOD AND POPULATION

IN recent years the British Association for the Advancement of Science has become increasingly aware of the necessity to re-align its activities to meet modern needs. Gone are the days when its annual meeting provided a forum for discoveries, great and small and made within the preceding twelve months, to be disclosed to an expectant world: radio, television and the scientific and technical press are only too anxious to publicize at once whatever discoveries are deemed to have 'news value'. But not only is the lay public bewildered by this bombardment; scientists themselves also find it increasingly difficult to assess the meaning and implications of work other than that in their own, often narrow, specialisms. The annual meetings of the Association have always provided a welcome opportunity for scientists in the many branches to meet one another and to make contact with an interested public. Now the Association is making a determined effort to present a balanced view of scientific progress to a wider audience—through its work with young people; its programmes of lectures at local centres, the new and attractive format of its bi-monthly journal, *The Advancement of Science*, and in other ways. At the Cardiff meeting a bold new experiment was tried. Coincident with the inauguration on July 1 of the five-year Freedom from Hunger campaign of the Food and Agriculture Organization of the United Nations, the Association chose as a central theme, to be emphasized by as many sections as wished, the numerous aspects of population pressure on land resources. A complete innovation was the suspension of all sectional programmes for one whole day—Monday, September 5—in favour of two plenary sessions of the entire Association in the Sophia Gardens Pavilion, devoted to a symposium on "World Food and Population".

Some 2,000 members assembled to hear the president, Sir George Thomson, open the proceedings. He reminded the audience that it was the success of medical science that necessitated a falling birth-rate to match the falling death-rate. It was not right that scientists should pass the problem to the politicians who, in any event, had to deal with the toughest and most resistant material in the world, human nature.

Dr. Norman C. Wright, deputy-director general of the Food and Agriculture Organization, presented the facts of the world food situation as they are known to that Organization. He drew a distinction between under-nutrition and malnutrition, and gave reasons for using calorie intake as a measure of under-nourishment. What proportion of the world's people can be described as under-nourished clearly depends on the standard taken. While British conditions suggest that 2,800 calories a day are necessary for the development of full health and vigour, requirements for the peoples of tropical climates, with lower average body-weights and stature, are clearly less. But 60 per cent of the world's population appear to have an intake of less than 2,200 calories, of which nearly half have less than 2,000 calories a day. With a poor harvest, under-nutrition passes very easily into semi-starvation and loss of mental alert-

ness, and even moral standards. Malnutrition accompanies under-nutrition, but is also found when the intake, though adequate in amount, is derived from an insufficiently varied diet—especially a shortage of protein from an all-cereal diet. Such malnutrition is reflected in the presence of several deficiency diseases—notably kwashiorkor—liable to affect children after weaning, that is, when they are transferred from a milk to a cereal diet. Dr. Wright urged that neither distribution of food surpluses from countries such as the United States nor a world-wide adoption of vegetarian diets could solve the problem—only the widespread and rapid application of recent scientific and technical advances.

Sir Alexander Fleck took up the latter point in the afternoon. Apart from advances in all kinds of techniques constantly being made, there is an adequate body of knowledge, and has been for many years, to secure sufficient food, indeed abundant food, for all mankind if only that knowledge is applied. There are six ways of producing more food: by extending the area under cultivation, substituting more suitable crops or varieties and animals or breeds, providing more water, more nutrients, adopting better techniques, and increasing efficiency of crop or animal use. A comparison of present-day yields, for example, between Japan and India in rice shows at once the enormous possibilities to be achieved by providing crops with adequate nutrients and water.

Both Sir Alexander and Prof. H. D. Kay—obviously through his extensive practical experience in recent years in many countries—stressed the human aspects of the problem: how to get right to the peasant cultivator to help him to help himself. The missionary spirit and the sense of dedication to a cause is nothing new to the British: both are badly needed to-day. Equally vital is the need to convert governments and administrations to the necessity for constructive agricultural policies. Too often agriculture is a Cinderella among government departments.

Prof. David Glass, speaking on the present trends of world population, stressed the double importance of focusing attention on the remainder of the present century, since by 2000 A.D. world population is most likely to increase to more than 8,000,000,000. Because of the present age-composition of the population in the less-developed countries, even such sharp reductions in fertility as might result from a rapid spread of birth control would not prevent very considerable increase in numbers by the end of the century. Even with a 50 per cent fall in live births in India during 1956–81, the population would still increase by more than 200 million by 1986. At present the evidence does not justify an assumption of a general fall in fertility: it is more realistic to plan for an increase of world population at the rate of at least 1.6 per cent per annum. Prof. Glass considered that we must be prepared for a very massive underpinning of planned economic and social development. Although he included emigration among the measures to be included, he noted that the present increase in world population in one year is about equal to the

net oversea migration from Europe in the 150 years 1800-1950. He noted, however, the symbolic value of emigration in promoting also economic and social change. In view of the relative ease of increasing food output in Western lands in mid-latitudes, the planned disposal of food surpluses in the West may be no less essential than the raising of agricultural productivity in less-developed regions.

Prof. Arthur Lewis, recently elected to the office of principal of the University College of the West Indies, discussed economic conditions for greater output under the four main headings of incentives, knowledge, capital and organization. He placed expanding demand first among incentives: rising standards of living in the towns demanding more food and more expensive foods. Provided the fruits of the farmer's labours accrue to him and not to the middle man or landlord, he doubted the importance of price stability, preferring freedom of prices to rise. Prof. Lewis was insistent on the enormous capital requirements needed in farming, but some of his assertions regarding organization can be questioned. In his own summary he asserted, "in most of Asia, where labour is abundant, mechanization contributes only where it brings under the plough land which could not otherwise be cultivated, or makes possible more crops in a year. Mechanization has more to contribute to the under-populated parts of Africa". He advocated subdivision of large properties, especially in Latin America, and considered that compulsion should be used when farmers are too ignorant and conservative to use better seeds or improved cultural practices, and advocated collectivization where necessary. As a West Indian who has a wide experience in many lands, it is interesting that Prof. Lewis more than any other speaker should advocate such forceful methods.

Prof. Dudley Stamp, speaking on land use and food production, stressed the contrast between a population not only increasing at an unprecedented rate—in excess of 45,000,000 a year—but also with rising standards of living, which meant both more and more varied food, more spacious layout of homes, facilities for recreation and movement and other extensive demands on land, with the known, fixed and broadly inextensible extent of the Earth's land surface which had to satisfy those many demands. While any part of the Earth's surface may have an economic importance through the occurrence of minerals, or for other reasons, the ecumene or habitable surface of the Earth having sufficient heat, moisture and soil to produce crops to support human life, is of limited extent. A fifth of the surface is too cold, a fifth too arid, a fifth too mountainous and a tenth soilless, so that only 30 per cent is potentially cultivable even if the many hazards of soil management in the tropics are overcome: at present each of the world's 2,900,000,000 inhabitants has a share of about 12.5 acres, or 4 acres 'potentially cultivable'. Of this, 1.1 or 1.2 acre is cultivated. Equating non-food crops with the contribution in food from the great open grasslands, it takes the produce of rather more than 1 acre to feed one human being. Against this world yardstick, extreme contrasts can be seen between one country and another—ranging, for example, from Canada with 140 acres a head, 21.5 officially classed as cultivable, with 3.5 used, or the United States (12.5, about 6, 3.0) to England and Wales (0.8, 0.6, 0.55) and Japan, where the food has to be wrested from a cultivated acreage of 0.17 acre a head. In some

countries it is clear that concentration on high-calorie foodstuffs and intensive cultivation is a national first priority; in most countries comprehensive land planning is the only sensible approach to the problem. Such planning must be based on objective surveys and mapping of existing land use (hence the importance of the world-wide scheme of the World Land Use Survey of the International Geographical Union) with an attempt to understand the reason for the present position and trends.

Prof. Stamp advocated further attempts to rate land of different types according to potential productivity and compared actual production by using a Standard Nutrition Unit of 1,000,000 calories farm production per annum (equivalent to a food intake of 2,460 per day) pointing out that 'carrying capacity of land' varies in even leading countries from less than 0.3 to 7 such units an acre. He appealed especially for fresh thinking in many directions, and by the many different sciences which have contributions to make. In particular he pointed out the fallacy of discussing 'over-population' unrelated to standards of farming technique—Britain has been over-populated at least since Norman times. A maximum population which could be supported is very different from the small body of experts which might most effectively produce the food. In erosion and flood control more emphasis should be placed on trapping and distributing eroded material where it could provide useful land. While it is desirable to preserve naturally good agricultural land and provide conditions where the microfauna and microflora can do their work without cost, why should not modern earth-moving machinery over large areas mix sterile sands and intractable clays to the right texture to receive the chemist's nutrients?

In the afternoon, after Sir Alexander Fleck and Prof. Kay had spoken, eight or nine speakers who had previously given in their names took part in a general discussion before Prof. P. M. S. Blackett wound up. Ritchie Calder remarked on the historic significance of the occasion—perhaps the first time in 120 years that the Association as a whole had got together to debate a problem of world-wide importance. Science had provided a vast super-market of knowledge: the user must have a thought-out shopping list. The common tacit assumption of the economists that efficiency in farming is to be equated with large-scale monoculture was voiced by Colin Clark, and brought vigorous headshaking from Dr. Kay; further, he doubted whether protein deficiency is widespread and whether many of the policies of the Food and Agriculture Organization are right—especially any encouragement of small-scale intensive mixed farming. Mr. James Callaghan, M.P., sharply reminded the Conference that a 5 per cent increase on prices paid for the agricultural raw materials of the 'under-developed' lands more than equalled all 'aid': guarantee their prices and forget 'aid'. Sir Charles Darwin felt that only part of the problem is being considered: man is an animal and behaves as such. With plenty of space there has been unparalleled expansion for two hundred years—the struggle for existence must come. Birth control may stave off the evil day, but is it not possible, he asked, that those who have believed in birth control would be the ones to go under? Prof. Sargant Florence, however, held that we do not want just to keep alive, but at a proper standard: we must increase production, but decrease reproduction.

In his summing-up, Prof. Blackett stressed four points: first, nothing we can do, short of nuclear warfare, can alter the fact that a great increase in population is inevitable in the near future; secondly, the technical 'know-how' exists; thirdly, there must be initiative and 'crash-action'; fourthly, the

educational aspect is vital and we should open the doors of our universities and technical colleges, however difficult it may be, more widely to overseas students. Finally, he felt that the day's useful discussions had ended on a note of restrained but robust optimism.

L. DUDLEY STAMP

AFFORESTATION OF INDUSTRIAL WASTE

THE sight of derelict land is all too familiar in the industrial areas of Great Britain, and the purpose of the session which was held in Sub-section K* (Forestry) of the British Association on September 2 in Cardiff was to explore the possibilities of afforestation as a land-use tool to improve the amenities of such areas. The three speakers looked at the problem from different points of view: that of a Forestry Commission officer, a planning officer of a county council, and a land agent to an owner of substantial areas of ironstone workings. It was refreshing to find that there was a large measure of agreement between all three as to where and in what circumstances afforestation could be usefully employed.

The symposium was opened by J. Q. Williamson of the Forestry Commission with a review of the evidence which has been built up over the past fifty years on the planting of trees on colliery spoil heaps. In his opinion the earlier doubts as to the success of such planting because of the probable lack of fertility of such apparently sterile sites has proved groundless. A large range of tree species can be planted successfully on tips so long as certain precautions are observed. The choice of planting species must first be governed by local conditions, particularly by the smoke pollution factor, which may rule out all conifers. Exposure is of great importance in tree growth generally, and the miniature mountains created by many spoil heaps could lead to severe exposure, especially if the heap happened to be already in an exposed position.

In areas where there is atmospheric pollution, birch, alder, sycamore, and in more fertile sheltered areas, ash and poplar, were recommended by Mr. Williamson as the most likely to succeed. Where tips are situated in more rural areas, over which the atmosphere is purer, conifers can also be grown, and this is much more attractive from the economic point of view. Of the conifers, Corsican and Austrian pine are usually to be preferred, but Japanese larch and Scots pine can also do well. His experience has shown that there is no special difficulty in establishing such species by normal forestry methods, but the trees must be looked after. Grazing animals must be rigorously excluded from the young plantations and, most important of all, the local population must be taught to cherish the young trees. Most failures in the past have been due to vandalism, and it is almost a waste of time to embark on a planting scheme unless there is a determined effort to guard the trees from damage during their early years. He recommended strongly that a programme of forestry education for the local population should accompany the planting of any colliery spoil heap, and if possible the local school children should be encouraged to take part in the actual planting and to look on the resulting woods as their own.

Mr. Williamson then gave details of the experimental afforestation of an open-cast coal site in Coed Morgannwg. He pointed out that by applying a restoration specification, which did not entail levelling and restoration of the top soil, a great deal of money can be saved. The result of this work had been most encouraging, and of the species used Corsican pine, Lawson cypress and Japanese larch among the conifers and common alder, grey alder and false acacia among the hardwoods had grown well. The trees on the more porous slopes had grown better than on the level ground where the passage of heavy machines had led to compaction of the soil.

After this technical appraisal of the problem, it was encouraging to learn from Mr. J. Casson, of the Planning Department of the Lancashire County Council, that the extensive work of afforestation carried out by his Department over the past nine years has led him to the same conclusions. He considers that there are thousands of acres in Lancashire alone which could be afforested with comparative ease and at not much, if any, greater expense than that incurred in establishing forest crops on normal sites. It is unfortunate that not many planning authorities in England and Wales have yet made use of Section 89 of the National Parks and Access to the Countryside Act of 1949 to undertake planting work aimed at enhancing the countryside. He considers that while the main objective of such a planting programme is the improvement of amenities, this work could obviously, to a greater or lesser degree, make a contribution to the economy of any area where forestry operations could be successfully carried out. The effect of enhanced amenities in checking emigration and attracting new industry could well be valuable in arresting economic decline; the converse is undoubtedly true—ugliness leads to emigration and discourages new industrial development. He looked on the work done in Lancashire up to the present as being mainly a fact-finding exercise to see how far forestry operations are practicable under various conditions of difficulty (climate, soil, pollution, etc.). They have located their siting in significant localities as experiments, not only in forestry, but also in the use of forestry as an instrument of land-use policy in the overall physical and economic rehabilitation of depressed and damaged regions. His Council's policy has been to acquire or plant under agreement without resort to compulsory purchase. While there is a wide choice of sites which might be planted in Lancashire, it is significant that land acquisition rather than technical difficulties has been the greatest problem in planning a forward programme. For every 100 acres planted, investigations and negotiations have been opened for 200–300 acres which have had to be

abandoned for one reason or another. Shifts in the value of waste materials and land, the presence of 'admitted' claims, conflict in the opencast coal-mining programmes, changes in legislation affecting land values and acquisition procedures, and the psychological factor that as soon as a public authority takes an interest in derelict land its 'value' often rises sharply, have all helped to hinder progress. In spite of this, he thought that it would not be justifiable to use the compulsory powers of the Act in the absence of any overall plan for rural afforestation and with such a wide choice of sites. The same arguments would not be so applicable in urban areas where town plans are well advanced.

More than 300 acres has been planted in Lancashire since 1951 under this scheme, and a great variety of sites has been tackled, varying from colliery spoil heaps, hematite waste and Gritstone quarries to degenerate woodland and bare land and moorland. The excellent slides shown by Mr. Casson and his forester assistant, Mr. L. A. King, illustrated very well the progress of the work and, although they had had their failures, it was obvious that, taken as a whole, this well-thought-out planting scheme has been most successful. Fourteen men are now employed on the work and a small nursery has been established to provide the necessary plants. With the development of 'know-how', they are increasingly able to introduce an element of landscape design into the work and they feel that they are now more successfully harmonizing economic, ecological and amenity aspects within a 'forestry' approach.

In spite of the very encouraging picture that was emerging, Mr. Casson admitted that there is a great deal still to be learned, and he made a strong plea that more scientific research should be done on the biological and technical problems posed by land dereliction, mineral working and the tipping of waste. He thought that such work would be of value not only to programmes of reclamation but also in the greater and increasing field of the planning control of the extractive industries. He realized that it is asking a great deal of local authorities to expect that they should embark on forestry schemes without the technical skills or documented data necessary to bring about a transformation in their derelict areas by using forestry; nevertheless, a great deal more could be done than was being done at present.

It was perhaps appropriate that Mr. Casson's inspiring talk on the tremendous possibilities of extending afforestation on industrial waste should be followed by a very factual account of the successful afforestation of ironstone workings in Northamptonshire on a really large scale. Mr. J. W. Houldsworth, land agent for the owners, Stewarts and Lloyds Minerals, Ltd., quoted chapter and verse of how more than 1,000 acres of land left derelict on 'hill and dale' after the ironstone had been extracted is now carrying flourishing plantations. This woodland area provides considerable amenity value to the nearby industrial town of Corby, as some of the earlier plantations are now 25-30 years of age and looking most attractive. Experience has shown that on the lighter soils a mixture of 40 per cent European larch with 40 per cent sycamore and 20 per cent Scots or Corsican pine is most suitable for the site, and the present intention is to leave the sycamore as a final crop after the gradual removal of the conifers. On the heavier boulder clay, common alder and occasion-

ally oak have been planted, but this latter species has been very slow growing.

A permanent staff of 20 men is maintained under a head forester and two foremen. The biggest problem facing the Company is not the establishment of plantations but the extraction of produce from them, especially as the size of pole increases as the plantations mature. Up to date there has been no difficulty in disposing of the produce, because a small estate sawmill is maintained for converting it into fencing material for use on the estate and quarries; a large quantity of the second-grade material goes into the steel work for loading strips.

Mr. J. W. Houldsworth was emphatic that, apart from the difficulty of extraction, the establishment and maintenance of plantations on this very unpromising waste present no particular problems; in fact there are certain advantages over normal forestry, as no weeding or cleaning is necessary on these bare 'soils'. His conclusion was that afforestation is the most economic solution to the problem of treating some of this worked ironstone land, and that it would prove a good long-term investment.

In the discussion which followed the papers, it was generally agreed that much more use could be made of afforestation in reclaiming industrial waste than had been done in the past. One of the main problems which perhaps makes public authorities a little reluctant to embark on ambitious schemes is the difficulty of making more than intelligent guesses as to what will grow successfully on any particular site. As each site usually varies so greatly within itself, the cost of extensive soil analyses is scarcely justified, and the general opinion of the meeting was that although more research should be undertaken on the constitution and plantability of the various types of industrial waste, there is now sufficient evidence to convince the most doubting authority that at least the easier sites could be planted with a fair degree of confidence.

The most controversial point discussed was the future treatment of plantations on waste land, once they were approaching maturity. Mr. Williamson thought that it would be of no use ever to consider clear felling and replanting, and advocated the introduction of some form of uneven-aged selection system in order that the soil was never bared and the amenity was maintained; but several others felt that there was no reason why such areas should not be clear-felled on maturity and then replanted, so long as attention was paid to shelter belts being left where necessary.

On the extraction problem in the plantations on the ironstone workings, the simple solution of using horses was suggested for at least the small- and medium-sized produce.

The growth of different species was discussed, sycamore and birch in particular, and it was agreed that both these species are difficult to establish; this accords with normal field experience.

This symposium did not minimize the difficulties which are present in the planting of industrial waste, where every site and every part of a site has to be considered separately; but there seems to be no doubt that enough knowledge is now available to encourage public authorities to embark on more ambitious planting schemes than they have ventured on up to date. The inspiring example of Lancashire will, it is hoped, lead to a more vigorous approach being made to this problem in many other parts of Britain.

J. Q. WILLIAMSON

INVESTIGATION OF THE UNIVERSE BY RADIO ASTRONOMY*

By PROF. A. C. B. LOVELL, O.B.E., F.R.S.

Jodrell Bank Experimental Station

ALTHOUGH nearly all the major advances in radio astronomy have taken place during the past fifteen years, the basic discoveries were made thirty years ago. At that time Jansky realized that the residual noise in his receiving equipment had a daily sidereal variation and must be the result of radio waves reaching the Earth from outer space, and Appleton in the United Kingdom with Breit and Tuve in the United States, through their studies of the ionosphere, laid the foundation of the radio-echo techniques of radio astronomy. The radio emission from outer space can be received on Earth in the wave-length range from a few millimetres to 10-20 metres. The short-wave end is limited by absorption in the atmosphere and the long-wave end by the ionosphere, and this upper limit tends to vary in sympathy with ionospheric conditions throughout the sunspot cycle. These hindrances will soon be overcome when suitable equipment can be carried in Earth satellites; then it should be possible to determine the true wave-length range of these extra-terrestrial emissions.

Here we are concerned with some of the significant advances made by the application of these techniques to the study of the solar system and the universe, with points of interest from the immediate environment of the Earth to the deepest penetration of the universe.

Some of the earliest successes with the new techniques arose from the study of the transient echoes which are obtained when a radio beam is directed into space. It was shown that these echoes originated from the scattering of the radio waves by the ionized trails of meteoric particles which were evaporating in the height-range of 80-120 km. above the Earth's surface. Methods were developed for the measurement of the velocities of these meteors and later for the determination of the orbits of individual meteor particles. A long-standing controversy was settled when it was shown that the sporadic meteors were members of the solar system and not visitors from interstellar space. New meteor showers active in the day-time sky were discovered and progress has been made in the basic problem of the genesis of this meteoric dust which pervades the solar system.

The extension of these radio echo techniques to the investigation of the Moon and the planets is a more recent activity which required the development of large radio telescopes and powerful transmitters. The lunar work has had two unexpected outcomes which arose from an analysis of the fading of the lunar radio echoes. One has been the discovery that the radio waves are effectively scattered from a rather small portion of the forward hemisphere of the lunar surface; and this led to the demonstration of the possibility of using the Moon as a reflector for round-the-world communication. The other was the proof that a component of the fading arose from Faraday rotation in the ionosphere which has led to

an important method for measuring the total electron content along the line of sight from the Earth to the Moon. The attainment of planetary echoes is still a difficult technical problem, and so far only limited success has been achieved in the case of Venus. The future of this work is full of promise since it may involve refinement of the value of the solar parallax, the determination of the rotation period of Venus and preliminary information about the nature of the planetary surface and atmosphere.

The emission from the Moon and many of the planets has now been measured in the radio-frequency range, and this has made possible a comparison of the black-body temperatures in the radio and visual regions. The measurements on Jupiter have been of particular interest for two reasons. First, it appears that the effective size of the disk depends on the wave-length, which indicates that the planet may be surrounded by radiation belts. Secondly, the planet exhibits a strong non-thermal and sporadic type of emission on frequencies below 30 Mc./s. The origin of this emission is unknown although it is believed that it may arise from a relatively few places on the planetary surface.

The Sun has been the most exhaustively studied single object in radio astronomy. Various types of emission in the radio-frequency range have now been delineated. The thermal component originates in the solar corona with an extension which depends on the wave-length. In the centimetric range the effective radius is similar to that of the solar disk with pronounced limb brightening. As the wave-length of observation is increased the effective size of the solar disk increases, until at wave-lengths of several metres the coronal radiation can be detected out to many solar radii. Various types of powerful sporadic emission are associated with sunspots and flares, and the mechanism of emission and the relation to the ejection of particles from the Sun remains an active subject of investigation. The recent results obtained by Simpson of Chicago in the American space probe *Pioneer V* have been of outstanding interest. In this work the cosmic rays from the Galaxy have exhibited a sudden decrease in intensity coincident with solar eruptions, radio emissions and geomagnetic disturbances, when measured at distances of several million kilometres from Earth.

The radio emission from the Milky Way has various origins, the study of which forms a major feature of contemporary research in radio astronomy. The most striking general feature is the resemblance of the intensity isophotes to the concentration of common stars. It has long been realized, however, that the common stars (even if they emit at all) do not contribute significantly to this radiation. The following classes of emission are now recognized:

(a) There are a number of localized, discrete sources of emission (radio stars) concentrated near the galactic plane. A few of these have been clearly associated with galactic nebulosities characterized

* Substance of a Royal Society Tercentenary Lecture, delivered on July 23

by a filamentary gaseous structure with violent internal motion. These include the three known cases of supernovæ (the Crab Nebula, and the supernovæ observed by Kepler and Tycho Brahe), and the most intense radio source in the sky in Cassiopeia. It seems likely that the Cassiopeia source and the other radio nebulosities may also be supernova remnants the initial outburst of which has not been recorded.

(b) There is a generally distributed emission observable over a wide range of wave-lengths the isophotes of which are similar to the stellar distribution. At short wave-lengths this emission has thermal characteristics and probably originates in free-free transitions from the movement of electrons in the field of the interstellar protons. At long wave-lengths the intensity and spectrum of the radiation are incompatible with such an origin, and this emission is believed to be synchrotron radiation arising from the relativistic motion of the electrons in the galactic magnetic field.

(c) Radio emission is observable from regions far beyond the galactic disk of visible stars. This halo or corona of emission is thought to originate in the same way as the long-wave radiation in the Galaxy, that is, from the relativistic motion of electrons in the galactic magnetic field.

(d) In 1951 observers in Leyden, Harvard and Sydney almost simultaneously established the existence of line emission from the neutral hydrogen clouds in the Galaxy on a frequency of 1420 Mc./s. This emission is associated with the transition between two levels in the hyperfine structure of the ground-state of the hydrogen atom. The two levels correspond with the two possible orientations of the electron spin in the magnetic field of the proton. The original suggestion was made in 1945 by van de Hulst, and since the practical demonstration of the existence of this line remarkable progress has been made, particularly by the Leyden school, in observations of the Doppler frequency shift and the derivation of the motion of the galactic hydrogen clouds. This work has given the first detailed insight into the spiral structure of the Galaxy, and is now in process of extension to determine the hydrogen content of extragalactic nebulae.

An important outcome of the existence of the observable hydrogen line emission is the possibility of measuring the galactic magnetic field by observing the Zeeman effect. The magnetic field should split the line into three components with an extreme frequency difference of 2.8 Mc./s. per gauss. Since the

interstellar field is not expected to be more than 10^{-5} gauss the maximum observable shift is likely to be of the order of 30 c.p.s. Experiments are in progress on this problem at Jodrell Bank, and so far an upper limit of 4×10^{-6} gauss has been set for the interstellar magnetic field.

Even a cursory inspection of the intensity plot of a high-resolution radio survey of the sky shows that there are prominent features which are not explicable in terms of the emission from the Milky Way. The most striking feature is the existence of large numbers of localized sources (radio stars) which seem to have a nearly isotropic distribution. A small number of these (two or three dozen) can be associated with the nearer normal types of extragalactic nebulae. The Andromeda nebula (*M* 31) has been studied in some detail, and as a radio emitter it is found to be essentially similar to the Milky Way, including the existence of an extensive corona around the Galaxy. Studies of the other spiral nebulae within the range of present-day radio telescopes are still in progress, but the existing evidence is that they also conform to this general pattern.

The problem of the majority of these isotropically distributed sources which are not associated with normal extragalactic nebulae is believed to be one of the most significant issues in astronomy to-day. It is thought possible that the failure to associate these with visible objects may be because they lie at very great distances in the cosmos. The direct evidence for this arises from a few cases where colliding or interacting nebulae at great distances have been associated with rather strong radio sources. The most outstanding case is that of the galactic collision in Cygnus at a distance of 700 million light years which is related to the second strongest radio source in the sky. The disparity between the visual and radio luminosity of this source is such that a similar event at ten times the distance could only be observed optically with great difficulty but would still be easily recorded as a radio source. Recently one of these radio sources, the apparent angular diameter of which is about 8 sec. of arc, has been related to a rich cluster of nebulae at a distance of 6,000 million light years with a recessional velocity amounting to 46 per cent of the velocity of light. The lecture concluded with a reference to the cosmological issues involved in this work, and to the experiments now in progress which are believed to be giving information about the condition of the cosmos at distances of many thousands of millions of light years.

A NEW THEORY OF THE ANGIOSPERM FLOWER

By DR. R. MELVILLE

Royal Botanic Gardens, Kew

THE interpretation of the Angiosperm flower as a structure built up from modified leaves bearing either ovules or microsporangia dates back to Goethe's essay on the metamorphosis of plants¹. Most attention and much controversy has been focused on the structure of the ovary, which in its simplest state was supposed to have been produced by the infolding of a leaf bearing ovules on its margin to form a box-like structure similar to the pod of a pea. The carpel

theory does account for many of the facts of floral structure; but numerous incongruities are glossed over or avoided by its proponents. Alternative theories have been put forward from time to time, one of the more recent being Saunders's theory of carpel polymorphism². This was shown to be untenable by Eames³, in a paper in which he expounded the modern form of the carpel theory, that assumes the primitive carpel to have been a palmate leaf

bearing the ovules on its lateral lobes. Even in the comparatively primitive flowers of the Ranunculaceae this theory requires the fusion of vascular tracts in the ovary, which presupposes a long and intricate evolution. Contrary to this, the Angiosperms spring into prominence in the Cretaceous, apparently after a sudden and rapid burst of evolution.

No fossil plants are known with carpels of either the pinnate or the palmate type. Only *Cycas* among recent Cycadales has a megasporophyll with the open pinnate carpel structure; but its microsporophylls bear no relationship to the Angiosperm stamen, and numerous anatomical differences distinguish it and other cycads from the Angiosperms. Although pinnate microsporophylls occurred in flower-like structures in the Bennettitales, the female organs associated with them differed so markedly from the Angiosperm gynaecium that this group, also, cannot be on the Angiosperm line of descent. The failure to find fossil precursors of the Angiosperms is commonly blamed on the paucity of the palaeobotanical record. Nevertheless, it is inconceivable that the most successful group of modern plants can have left no trace of its ancestors in the rocks. Darrah⁴ believes "that we have most if not all of the clues to Angiosperm origin, but botanists have not been able to put them into a logical story". It is unlikely that they could do so if the carpel theory were based upon false premises.

Starting with the one assumption—that the carpel theory might be wrong—a re-investigation of the vascular structure of the flowers of a range of Angiosperm families has been made. Bleaching and clearing techniques have been used for obtaining preparations in which the complete vascular system could be examined as a three-dimensional object and the exact relationship of its parts determined. Out of this work arose the conviction that the basic structure of the Angiosperm ovary was a leaf bearing on its midrib or petiole a dichotomous fertile branch. From this structure, or its simple derivatives, the gynaecia of all modern flowering plants could be easily formed. The basic structure of the male organs was similar, but, not being restricted by the function of enclosing ovules, more primitive stages in the evolutionary sequence have survived in the andræcium than in the gynaecium. To obviate confusion, it is proposed to avoid the term 'carpel' and to call the basic structure a 'gonophyll'. The male, female and bisexual analogues may then be called 'androphylls', 'gynophylls' and 'androgynophylls'. The theory may be called the 'gonophyll theory'.

For brevity it will be convenient here to present the theory as a 'logical story', leaving the detailed evidence for separate papers on the gynaecium and andræcium to be published elsewhere. The Psilophytales of Silurian to Devonian age may be taken as the starting point. In the simpler members of this group such as *Rhynia* and *Horneophyton*, the plant body was a leafless dichotomous branch system bearing terminal sporangia (Fig. 1). Zimmermann⁵ derives all megaphyllous leaves from dichopodia of the Psilophytalean type, by overtopping, planation and fusion. Some of the early stages in these very generalized processes are to be found in the Psilophytales and in the Coenopterid ferns of the Devonian and Carboniferous, while later stages survive in modern ferns and Angiosperms. The development of the megaphyllous leaf used up one of the branchings of each dichotomy, so that, instead of a diffuse

branch system, there was a tendency to produce a single main stem bearing a succession of leaves. The main stem dichotomized only occasionally as in *Lyginopteris oldhamia*⁶, a habit which has been retained in living cycads and palms. Other plants of the Carboniferous period developed another kind of branching, which proved to be of great significance for the evolution of the higher plants. Early examples occur among Coenopterid ferns, where, as in *Ankyropteris grayi*⁶, the petiole trace rounds off to give rise to a stem-like structure shortly after its departure from the stele of the main stem. It then forks, the abaxial part supplying the leaf and the adaxial forming a branch. Thus arose the leaf-branch combination, which formed the repetitive unit in this new kind of branch system.

It is likely that the epiphyllous branch first arose as a reproductive structure, though little fossil evidence on this point has come to light. Excluding adventitious shoots, the only epiphyllous shoots surviving in modern Angiosperms are reproductive in function. An incomplete list of genera in which they are found is given by Velenovsky⁷. The fertile branch may be reduced to a single flower bearing the same relationship to the leaf as the branch of *Ankyropteris*. Examples are to be found in several genera of Epacridaceae, where, as in *Andersonia*, the terminal leaves are fertile and those immediately below have epiphyllous buds in the corresponding position. Here, and in the Chaillotiaceae studied by De Candolle⁸, the axillary bud appears to have evolved by the sterilization of an epiphyllous inflorescence (Figs. 13, 14). Theoretically, axillary buds could have arisen also by the condensation of compound branch systems composed of the primitive leaf-branch units, but evidence for this alternative is lacking.

The first and sometimes some of the later branchings of the epiphyllous inflorescence in the Chaillotiaceae are dichotomous. The main peduncle may be relatively long, or the primary dichotomy may be sessile or sub-sessile on the petiole. The peduncle, also, may vary in position even in a single species, so that at times it may take up a truly axillary position. If the peduncle is then reduced until the dichotomy is sessile, a pair of fertile branches in a single leaf axil results. Both epiphyllous and axillary inflorescences occur in *Dichapetalum pedunculatum* (Aubl.) Baill. and pedunculate and paired axillary inflorescences in *D. timoriense* (DC.) Boerl. and other species. The anatomy of these epiphyllous inflorescences indicates that they are not due to adnation, but that leaf and inflorescence stalk fuse into a single structure, which repeats, in all essentials, the condition in *Ankyropteris*. Further evidence for the view that the Chaillotiaceae have retained a primitive form of attachment of the inflorescence is provided by other fossils. Whereas the primitive epiphyllous branch is found in *Ankyropteris grayi* of Lower Carboniferous age, paired axillary branches occur in the later *A. glabra* of Upper Middle Pennsylvanian age⁹. Parallel evolution of simple and paired axillary branches took place in the Cordaitales, where the simple branch is usual, but paired branches occur in *Mesozylon biforme* Baxter¹⁰. Other groups may have followed a similar path. Rather specialized epiphyllous inflorescences have recently been described by Plumstead^{11,12} for the Glossopteridales. There is positive evidence, therefore, for the existence at the end of the Carboniferous or early Permian of plants with epiphyllous, simple axillary and paired axillary

Figs. 1-38 Evolution of the components of the gynoecium and androecium of the Angiosperm flower. 1, Dichopodium with terminal sporangia, Psilophyalean phase; 2, Condensation to branch system with sporangia epiphyllous on leaflets; 3, Primitive gynophyll, a leaf with complex epiphyllous ovuliferous branch; 4-7, Reduction series giving foliicles, legumes and achenes by enfolding; 8-11, Separation of the ovuliferous branch from its blade and reduction; 12, Enclosure of branchlets of ovuliferous branches by alternate whorl of sterile blades or tegophylls; 13, Epiphyllous vegetative bud, Epacridaceous type; 14, Axillary vegetative bud, usual Dicotyledon type; 15, *Glossopteris* (*Scutum*), an androgynophyll with foliaceous male and female branches; 16, *Gnetum*, an androgynous branch adnate to the inflorescence axis; 17, *Magnolia*, androphylls and gynophylls with adnate branches; 18, Catkin scale of *Populus*, an androphyll with cupular fertile branch with reduced bract; 19, *Homalanthus*, cupular fertile branch with reduced bract; 20, *Salix pentandra*, elimination of bract and reduced number of stamens with staminodes; 21-22, Theoretical reduction to single aphyllous stamen; 23-27, Reduction of pinnate androphyll; 28, *Juglans*; 29, *Corylus*; 30, *Carpinus*; 31, *Prunella*, primitive androphyll with many complex branches (one shown), *Ricinus* type; 32-33, Reduction to aphyllous stamen; 34, *Malvaceae* (*Sparmannia*); 35, *Malvaceae* (*Hibiscus*); 36, *Rhamnaceae* type; 37, *Ranunculaceae* type; 38, *Ranunculaceae* type; 28, 33, 35-38, Euphorbiaceae; 35, *Mercurialis*, male flower; 37-38, *Euphorbia* spp., male flowers; 34, Rosaceous type androphyll-sepaloid. The examples cited indicate evolutionary stages—not lineages. To avoid confusion, the full complement of stamens is not shown in Figs. 18, 19, 23, 28.

inflorescences. The elements necessary for condensation into modern flowers were already present.

In the primitive form of the gonophyll, the leaf-branch unit was repeated many times (Fig. 2). The structure could be condensed in a variety of ways. The male and female organs could be confined to separate parts of the branch system of one gonophyll, or separated completely on different gonophylls. The foliar part of the dual combination could be suppressed in the secondary gonophylls of the fertile part, giving rise to an epiphyllous ovuliferous branch on the primary gonophyll blade (Fig. 3). The same processes, carried further, would produce axillary ovuliferous branches and then ebracteate ovuliferous branches (Fig. 9), which in turn could become associated with sterilized gonophylls in alternating whorls (Fig. 12). Thus could the elements of the modern Angiosperm ovary come into being.

The simplest kind of ovary was formed by folding the blade of the gonophyll around the ovuliferous branch system, which usually dichotomized somewhere near the base. The legumes of the Papilionaceae and the achenes of *Thalictrum* and *Ranunculus* (*Ranunculaceae*) have this structure, the number of ovules varying from many to one. Fusion of a number of such units gave rise to a multilocular ovary, as in *Oxalis* (*Oxalidaceae*) and *Triglochin* (*Juncaginaceae*). In a number of families, the ovary has been formed from sterilized gonophylls, which may be called 'tegophylls', alternating with bifurcated ebracteate ovuliferous branches. With this arrangement, a tegophyll encloses one of the branches of each of the adjacent ovuliferous branch systems (Fig. 12). If the ovuliferous branch bifurcates near the base, the ovary may be a collection of foliicles, as in *Caltha* and *Helleborus* (*Helleboraceae*), or the foliicles may be

more or less fused, as in *Butomus* (Butomaceae). When the ovuliferous branch bifurcates at a higher level, the undivided part may take up an axial position and the components of the ovary are clamped together by the enfolding of the adjacent branches in the upper part, as in *Buxus* (Buxaceae). Simple unilocular ovaries with parietal placentation are formed from alternating components by the overlapping of the margins of the tegophylls and the application of the ovuliferous branches to the wall so formed, as in *Berberidopsis* (Flacourtiaceae). Another class of ovary may be formed by simple apposition of the margins of fertile gonophylls. *Koelreuteria* (Sapindaceae) has this structure, false septa between the axial ovuliferous branches and the midribs of the gonophylls helping to hold the components together. A number of modifications of these basic types of structure are to be found in particular families. Similar principles apply to inferior ovaries, with the added complication of adnation and fusion of vascular strands of the ovary with those of the enclosing sepals and petals. This aspect of inferior ovaries is not in dispute and has been described and illustrated by Eames³.

It is necessary now to return to the primitive androphyll and follow its evolution into modern types of andræcium. Starting with the 'gonophyll of gonophylls' (Fig. 2), a primary gonophyll blade may be retained and the secondary gonophylls with their blades condensed into another expanded leaf-like structure bearing the terminal fertile organs on branches arising directly from its surface and attached to its dichotomous vascular system. This structure is found in the individual male flower of *Populus* (Salicaceae) (Fig. 18), where the vascular system of the 'perianth' branches off from that of the bract, which represents the primary androphyll blade. Essentially the same structure occurs in *Homalanthus* (Euphorbiaceae) where the bract is much reduced (Fig. 19). The bract is eliminated in *Salix* (Salicaceae) (Fig. 20), where the catkin scale represents the secondary blade or the 'perianth' of *Populus*. In *Salix* the number of fertile stamens varies from twelve to two in different species. The nectaries of *S. pentandra* L. are staminodal stumps retaining vestiges of their vascular system, which, by their mode of attachment to that of the bract, indicate their derivation. Further reduction in this series would lead to an androphyll with one stamen (the *Rhamnus* stage—see below) and then to a simple aphyllous stamen (Figs. 21, 22).

If the original compound gonophyll were bisexual, the condensation could take the form of a leaf bearing a pair of leaf-like structures, one male, the other female. These would be opposed on the primary dichotomy of the epiphyllous branch and their ovules and micro-sporangia would be attached to the opposing surfaces. This structure is exactly that of the *Glossopteris* fructifications (Fig. 15) of Lower Permian age recently described by Plumstead^{11,12}. Although palaeobotanists have not unreservedly accepted her interpretation, the continued existence of similar unisexual structures is in its favour. Moreover, the presence of a once bifurcated branch arising in the opposed position on the adaxial side of the vascular system of the 'perianth' in the staminate flower of *Populus canescens* L. (Fig. 18) is in the position it would need to be if it were derived from a sterilized female branch. Thus the possible origin of the male flower of *Populus* from a primitive

bisexual structure of the *Glossopteris* type is an open question. The present evidence suggests that *Glossopteris* must have been very close to the pro-angiosperm stock at that level of evolution.

The bisexual condition is found also in the androgynous inflorescences which often occur on male plants of *Gnetum*¹³. They probably represent the primitive condition in the Gnetales. Here, there is a fertile branch attached to the vascular trace of the bract, but it is adnate to the inflorescence axis (Fig. 16). Allowing for the modifications due to adnation, this arrangement is similar in essentials to that found in the Glossopteridales and suggests a relationship with that group. Adnation of the fertile branch to the main axis is found again in the flower of *Magnolia* (Fig. 17). The sepal of *Magnolia* is an androphyll bearing stamens in a manner similar to *Gnetum*, but the tip of the fertile branch trace continues upwards and fuses with a small branch arising from the ovuliferous branch of the follicle above. The latter is produced by the enfolding of a gonophyll of the type shown in Fig. 6. After the anastomosis, the branch trace continues upwards and fuses with the corresponding branch of the follicle next above. In this way, the main stele of the floral axis is enclosed in a network of vascular traces resembling a dictyostele, through the meshes of which the follicles protrude. The similarity of the staminate part of the *Magnolia* flower to that of male *Gnetum* in the essentials of its vascular structure suggests that the Gnetales and the Magnoliales are divergent offshoots of a common stock. Thus, there is at last evidence to link the Dicotyledons with the Gymnosperms through their reproductive organs.

Another type of condensation of the primitive system could lead, by overtopping and planation, to a pinnate leaf-like structure bearing fertile branchlets on the leaflets. Reduction of the fertile branchlets to single stamens would then lead to the condition found in the individual catkin scales of *Juglans* (Juglandaceae) (Fig. 23). Further reduction of this to the three-lobed condition would give the catkin scale of *Corylus* (Corylaceae), in which two stamens are borne, one each on the two main branches of the vascular system of the terminal lobe and three on each of the lateral lobes (Fig. 24). There is no aggregation here into a flower-like structure, but *Alnus* (Betulaceae) is more advanced in this respect. In it, the subtending scale bears three flower-like structures consisting of four scales, each with a single epiphyllous stamen. Further condensation in the Corylaceae leads to the fusion of the three lobes of the catkin scale into one in *Carpinus* (Fig. 25) with relegation of the stamens to the basal portion of the vascular system. The logical end-points of this sequence, again, would be an androphyll with a single stamen and then an aphyllous stamen (Figs. 26, 27).

Yet another type of condensation of the original compound gonophyll would lead to a flat blade with several fertile branches of one sex attached to it. Such is the condition of the perianth lobes of the male flowers of *Ricinus* (Euphorbiaceae) (Fig. 28). The complex staminal branches are dichotomous systems in which the terminal branchlets bear a pair of anther sacs on either side of a minute leafy blade, here interpreted as the ultimate androphyll with a pair of microsporangia. Numerous stages in the reduction of this complex androphyll occur in the Euphorbiaceae, leading to androphylls (perianth lobes) with three or four stamens in *Mercurialis*

(Figs. 35, 36) and three, two or one in *Dalechampia*. These male flowers have an absciss layer below the perianth. They are borne in complex inflorescences capable of a second cycle of reduction, which may lead from a flower of the *Mercurialis* type to one with three perianth lobes and one stamen (Fig. 37) and thence to the unistaminate male flower of *Euphorbia* (Fig. 38) with no perianth, but an absciss layer in the middle of its stalk¹⁴.

Reduction of an androphyll of the *Ricinus* type could take two other paths. In one, the compound branches would be reduced to single stamens, so producing a blade with a variable number of simple stamens distributed over its surface. A whorl of five of these relatively primitive structures fuse together to form the sepals and perigynous cup of the Rosaceae (Fig. 34). The petals in this family are sterile structures, probably evolved from androphylls of the same kind. The second type of reduction leads to an androphyll bearing in a median position on its surface a single dichotomous branch system, each branchlet terminated by a stamen. This condition occurs in the Tiliaceae (Fig. 29) and Malvaceae (Fig. 30), where the stamens are grouped in dichotomous systems attached to the petals, with filaments free in the one and adnate with those of adjacent petals into a column in the other. Either of these types of androphyll could lead by further reduction to a single epipetalous stamen, as in *Rhamnus* (Rhamnaceae) (Fig. 31) and finally to a single aphyllous stamen attached at a 'leaf-gap' to the floral axis, as in *Ranunculus* (Fig. 32).

The vascular structure of the flower provides evidence for a number of evolutionary lines within the Angiosperms. The primary diversification of the pre-angiosperm stock appears to have taken place during its gymnospermous phase in the late Carboniferous or early Permian. Many Angiosperm lineages must date back to this period as distinct lines of evolution, so that, in this sense, the Angiosperms are polyphyletic. Already the new theory is throwing much light on Angiosperm phylogeny. The great disparity between the floral vascular systems of Ranunculaceae and Magnoliaceae, indicating an origin from widely divergent modifications of the gonophyll structure, implies a very ancient separation of these stocks. A number of other lineages must be as old.

From its mode of origin it might be anticipated that derivatives of the gonophyll would be found in parts of the plant other than the gynaecium and androecium. Reference has been made above to staminodal nectaries, but the nectarial flap of the *Ranunculus* petal is not obviously of this origin. It is often provided with a vascular trace¹⁵, which is opposed to the petal trace, as it would be if it had originated from an epiphyllous branch. The petal of *R. gunnianus* Hook. has several nectarial flaps, which indicates the probable origin of the *Ranunculus* petal from an androphyll of the rosaceous type (Fig. 34). Other structures with opposed vascular systems are the coronas of the perianth of *Narcissus*¹⁶ and of the sepals and petals of *Passiflora*¹⁷. In the latter, the vascular system of the corona is often elaborately dichotomous and apparently little altered from that of its gonophyll precursor.

The flower and inflorescence are both condensation products of the primitive gonophyll of gonophylls. As in the flower, condensation of the inflorescence has taken many paths. Sometimes evidence of the epi-

phyllous origin of the fertile branch is retained in the attachment of the flower to some part of the vascular system of its bract (Epacridaceae, Proteaceae). The compound female inflorescence of *Dobinea delavayi* Baill. (Anacardiaceae)¹⁸ provides a striking example in which the individual flowers are attached to the centre of a rounded dentate bract reminiscent of the fertile scale of *Glossopteris* (*Scutum*). Allusion has been made already to the occurrence of epiphyllous inflorescences in a number of families. DeCandolle's study⁸ of the Chaillietaceae indicated that the epiphyllous inflorescence of this family is not adnate to the leaf, but is part of it and that all stages in the detachment of the inflorescence from its leaf occur, leading to the axile position. Similar evidence is to be found in other families.

In this brief summary of the gonophyll theory it has been possible to cite comparatively few examples. It is hoped, however, that enough has been said to illustrate the scope of the theory in explaining not only the gynaecium but also other parts of the flower and the inflorescence. Many facts that formerly appeared to be anomalous in the context of the carpel theory now fall naturally into place. For the first time it is possible to indicate a link between the reproductive structures of *Gnetum* and those of Angiosperms and to point out similarities between those of *Glossopteris* and the androecium of certain Angiosperms.

In conclusion, it is my pleasure to acknowledge the help of my daughter, Mrs. F. A. Wrigley, in making preparations for the study of the gynaecium, and of my colleagues at the Royal Botanic Gardens, Kew, for many stimulating discussions and for directing my attention to relevant plants and literature.

OBITUARIES

Dr. C. E. Kenneth Mees, F.R.S.

WITH the death of Dr. C. E. Kenneth Mees on August 16, at Honolulu, Hawaii, at the age of seventy-eight, the world has lost a major pioneer of industrial research. To-day industrial research is fashionable, and many good scientists are attracted to it. Things were very different in 1906 when Dr. Mees joined the small firm of Wratten and Wainwright, makers of photographic plates. He had just emerged from a brilliant university career with degrees of B.Sc. and D.Sc., both by thesis in collaboration with Samuel E. Sheppard under Sir William Ramsay of University College, London. Sheppard adopted the

more usual course and went to Germany to continue academic research, though he rejoined his old colleague later to continue an association which lasted throughout Sheppard's life. Mees turned to industry for reasons which he afterwards stated to be political. The son of a Wesleyan minister, he was a Fabian who realized that an equal sharing of wealth, while effectively depriving the rich, would do little to benefit the poor. What was needed was a general increase in the standard of living, and this he believed could be achieved only by the application of science to industry. An experience from the Wratten and Wainwright days can now be seen to epitomize what he considered should be the objectives of industrial research. Mr. Wratten had told him that plate prices were being cut, profits were diminishing and that he must devote his energies to reducing their manufacturing cost. Mees completely ignored these instructions. The blue-sensitive plates of the day were being bathed by the user in solutions of dyes to make them sensitive to longer wave-lengths. He found out how to incorporate this step during manufacture and proceeded to market outstandingly good panchromatic plates at a premium price with great benefit to the Company's profits. Throughout his subsequent career he was always aiming to open up new markets with new products; others could worry about holding existing markets. In another way these early years in industry set the pattern of what was to come, in that despite his many pre-occupations with commercial problems, he found time to publish several scientific papers of importance.

He had made himself so indispensable to Wratten and Wainwright's that when, in 1912, George Eastman wanted his services in order to found a research laboratory, he had to purchase the Company. His subsequent career with the Eastman Kodak Co. continued until he retired in 1955, seeing him appointed a director in 1923 and vice-president in charge of research in 1934. He became internationally recognized as a pioneer in industrial research and a great exponent of it. The reputation of his laboratory in Rochester, New York, grew by his insistence on high standards and on the publication of the results of research. The decision whether to publish or not was based on the principle that results of value to science ought to be published. This was in line with his belief that industry should repay its debt to pure science, in accordance with which belief he undertook to supply special—and unprofitable—plates to astronomers and started the manufacture of Eastman organic chemicals when the United States was cut off from German supplies during the First World War—a service still valued by organic chemists everywhere. He established research laboratories in the Company's subsidiaries in England and in France and was a frequent visitor to Europe.

Mees's influence on the commercial success of the Company was equally great, and he was largely responsible for such outstanding contributions as the introduction of amateur cinematography and for the popularization of colour photography in all its forms. Of his personal work, apart from many scientific papers, must be mentioned one of the earliest books on the organization of industrial research, published in 1920, which was brought up to date much later by the publication in collaboration with John A. Leermakers of "The Organization of Industrial Scientific Research". His greatest contribution to scientific literature was the "Theory of the Photographic

Process" (1954), which had its origins in the book published in collaboration with Sheppard based on their research theses in 1907 which became known simply as "Sheppard and Mees". Recognition of his work was made plain by his receiving from almost every scientific body connected with photography their highest awards, by his election to the fellowship of the Royal Society (1939) and to membership of the U.S. National Academy of Sciences on becoming an American citizen in 1950.

Perhaps Mees's outstanding characteristic was his insistence on the importance of facts and his ability to analyse their implications. It was for this reason that in debate he could be a devastating opponent, but if it could be shown that the facts were against him he cheerfully accepted, not defeat, but the new circumstances. Mees usually dominated any group in which he found himself, mainly by the clarity with which he saw any problem (and the solution to it) and the consequent forcefulness with which he could express himself. He once gave the advice to one of his men, who was writing a book: "If you don't know for certain, don't say it; if you must say it, be dogmatic!" He was widely read, an authority on many subjects, ranging from astronomy to the history of ancient Egypt, having as a central theme the growth of science and technology through the ages. This interest led to the publication in 1946 of "The Path of Science", written in conjunction with John R. Baker. He was a brilliant lecturer, as those who remember his Royal Institution Christmas lectures in 1935 will know, and a stimulating conversationalist. His views on the organization of industrial research were widely sought by other directors of research and by industrialists. They can well be summed up as insistence on the importance of the individual. He had no use for the idea that research had to become a team effort, and he believed that the youngest of men could do worth-while research if given the opportunity, as he had indeed proved in his own case. He surrounded himself by many brilliant individualists, gave them the freedom such men require, and regarded his job as the protection of these men from the direction of others rather than the direction of their work by himself. He asked the Company to judge by the end-results. It had no regrets.

Mees married in 1909 Alice Crisp (she died in 1954), by whom he had a son and a daughter.

E. R. DAVIES

Dr. R. C. Farmer, O.B.E.

THE death of Dr. R. C. Farmer on July 30 at the age of eighty-two has removed one of the great pioneers from the world of military explosives. He was well known not only for his contributions to the defence of the State but also for his publications, which appeared over a number of years in scientific journals. It is remarkable that his last three papers were printed in the *Journal of the Chemical Society* when he was within a few weeks of eighty-two. He married, in 1908, Maud Mary, daughter of Mr. T. T. Sharpe, of Liverpool, and had two sons and one daughter, all of whom have taken up scientific work.

Robert Crosbie Farmer was born on November 30, 1877, in Liverpool, where he received his early education and later graduated with first-class honours at the University. With the aid of scholarships he studied at Wurzburg under Hantzsch and Röntgen, and was awarded the Ph.D. (*summa cum laude*) for

his work on the tautomerism of hydrazones and oximes. After a short spell as analyst in a paint works, he entered the University of Birmingham with a Priestley scholarship and worked on the use of liquid nitric peroxide as a solvent for organic compounds. He also developed a new way for measuring hydrolytic dissociation (partition method). Afterwards he was appointed lecturer and demonstrator and was awarded the degree of M.Sc. (Birmingham and Victoria).

In 1902 he became principal assistant to the late Dr. O. J. Silberrad at the Experimental Establishment of the War Office Explosives Committee (later Research Department, Woolwich), of which Lord Rayleigh was president and Sir William Crookes a member. His earliest work was on the mechanism of the decomposition of nitrocellulose and on cordite Mk. 1, which had ignited spontaneously in several magazines in India. This work was embodied in his thesis for a D.Sc. (Liverpool). When Dr. Silberrad left in 1906, the vacant post was offered to Dr. Farmer, but serious ill-health at that time prevented his acceptance and Dr. (later Sir) Robert Robertson was appointed. During the ensuing years he continued his work on the chemical stability of explosives and developed the vacuum stability test for high explosives, a test which is now regarded of first importance in considering their suitability for Service use. When War started in 1914, he devised a process for the manufacture of trinitrotoluene which was used on the largest scale in Government factories and by several private firms. Early in 1915 he was transferred to the Department of Explosives Supply

and became chief chemical adviser to the director general, Lord Moulton. In this capacity he was responsible for guidance to manufacturers and safety of processes, several of which he improved. He had control of extra-mural research in this field at the universities and was a member of many committees, including those on Munitions Inventions and Nitrogen Products.

At the conclusion of the War in 1918 he was made O.B.E. and received a Russian decoration, the Order of St. Anne. He left the Government service, forfeiting all rights to pension, and became a director of W. J. Bush and Co., manufacturers of fine chemicals. In 1922 he accepted an invitation to return to the Research Department as deputy director of explosives research and later became chemical adviser. In these capacities he was largely responsible for organizing researches and dealing with a multitude of technical problems arising in the Fighting Services. He represented the Department on a number of committees, including those on Adhesives and Forest Products under the Department of Scientific and Industrial Research, and for some years was a member of the Council of the Institute of Chemistry. On retirement he continued research work at King's College, London, up to his last years.

Dr. Farmer was of a lovable disposition and sacrificed all considerations of self to duty. He had abundant wit and his speeches on lighter occasions were masterpieces. His recreation was walking. No one can be more indebted to him for his generously given help through strenuous years than myself.

GODFREY ROTTER

NEWS and VIEWS

Bacteriology at University College Hospital Medical School:
Prof. Wilson Smith, F.R.S.

PROF. WILSON SMITH is retiring from the chair of bacteriology at University College Hospital Medical School, a position he has occupied since 1946. Prof. Smith is a Manchester graduate, having qualified in 1923. In 1927 he went to work at the National Institute for Medical Research at Hampstead and soon came to the fore as a contributor to knowledge about viruses, particularly vaccinia and herpes. In 1933, with P. P. Laidlaw and C. H. Andrewes, he demonstrated that influenza virus would infect ferrets, a discovery which opened the way to a laboratory investigation of the disease; and in the following years these three workers laid the foundations of present-day knowledge of influenza in its laboratory aspects; they soon found that the virus would infect mice, could be grown in fertile eggs and in tissue culture and could be studied by means of various serological tests. In 1939 Wilson Smith was appointed to the chair of bacteriology at the University of Sheffield, but returned to London in 1946 to the chair which he is now vacating. With

various collaborators he has continued to work on influenza, particularly its serological aspects, and on poliomyelitis. His contributions have not only been to virology, however, but also to bacteriology. He was elected to the fellowship of the Royal Society in 1949 and has twice served on its council. He delivered the Society's Leeuwenhoek Lecture in 1957 on "Virus-host Cell Relationships".

Prof. G. Belyavin

PROF. WILSON SMITH is succeeded in the chair of bacteriology in University College Hospital Medical School by Dr. George Belyavin, who is at present senior lecturer in that department. Dr. Belyavin was educated at St. Paul's School and the Westminster Hospital,

from which he graduated M.B., B.S. in 1943. He was awarded the M.D. in 1960. During 1944-46 he acted as resident pathologist to the Westminster Hospital, and from 1946 until 1949 he was a member of the Department of Biological Standards of the National Institute for Medical Research, Hampstead. Since 1949 he has been continuously at University College Hospital Medical School. Dr. Belyavin has had two main research interests—immunology and virology which, as his

Messrs. Macmillan announce that, as from January 1, 1961, the subscription price for *Nature* will be £8. 8s. per annum and *pro rata*. The price of single issues remains 2s. 6d.

published work shows, he has been able to combine successfully. He has been concerned with the mechanism of the antibody response, and in collaboration with Prof. Wilson Smith he has studied the kinetics of the formation of different types of antibody in response to infection with poliomyelitis and influenza viruses. Recently, he has investigated the immunological response in Hashimoto's disease in collaboration with Dr. W. R. Trotter, and has identified the antigen responsible for the positive complement fixation test in this disease. A major interest for some years has been the study of the antigenic characters of influenza viruses and factors in normal sera which combine with these viruses.

Atomic Energy Research Establishment: Solid State Physics Division

A SOLID State Physics Division has been formed at the Atomic Energy Research Establishment, Harwell. Its initial term of reference will be: to carry out basic research leading to greater knowledge and understanding of the structure and behaviour of solids. Dr. W. M. Lomer, at present head of the Theoretical Physics Division, has been appointed head of the new Division. Dr. W. C. Marshall, at present a group leader in the Theoretical Physics Division, is to succeed Dr. Lomer as head of the Division.

The formation of the new Solid State Physics Division reflects the importance which the Authority attaches to a better understanding of the structure and properties of solids. The nuclear reactors at Harwell, and particularly the research reactor *Bepo*, and the materials testing reactors *Dido*, *Pluto*, play a very important part in studies of the properties of materials. The programmes of work fall broadly into two parts. First, there are basic and applied studies of the effects of nuclear radiation on materials of decisive importance to reactor technology: this work will remain under the control of existing Harwell Divisions, particularly the Metallurgy Division. Secondly, there are more basic studies of the behaviour of solids in general, without reference to any particular application in reactor technology: this work will be the special concern of the new Division. It will include studies of the formation and nature of defects in crystals; other physical properties of metals, alloys and magnetic materials; and fundamental crystal physics using extracted beams of neutrons from the Harwell reactors.

The International Atomic Energy Agency

IN a statement issued in Vienna on the third anniversary of the establishment of the International Atomic Energy Agency, Mr. Sterling Cole, its director-general, said that the experience of three years had demonstrated that a balanced development of the peaceful uses of nuclear energy could be achieved only by international co-operation on the widest possible basis. It was now apparent that the development of reactors, and in particular power reactors, would take considerably longer than was originally expected, but progress in the use of radioisotopes and other radiation sources had been rapid and substantial, especially in industry and medicine. Early hopes that nuclear power would soon become an effective instrument for the rapid industrialization of under-developed countries had been somewhat hampered, and in assisting such States the Agency at this stage was more concerned with preparing the

groundwork than with advanced projects. Technical assistance and training were now two of its most important programmes; the exchange and dissemination of information was another developing function; and its research problem was mainly concerned with problems of radiation protection.

The Russian Earth Satellite 1960a

REFERENCE was made in *Nature* of September 3, p. 830, to the Earth satellite (1960a) or *Sputnik 5*, on the basis of reports then available. This satellite was launched on August 19 at about 0845 hr. U.T., and consisted of the 'space capsule' itself, and the last stage of the launching rocket. The two objects were seen from the United Kingdom at about 2113 hr. U.T. on August 19 with apparent magnitudes of +3 and +6, the fainter object following the brighter in the same orbit, with a separation of about $\frac{1}{2}^{\circ}$ —whether the brighter or the fainter object was the 'capsule' is not certain. Transmissions from the satellite on frequencies of 19.995, 39.990 and 59.985 Mc./s. were received by staff of the Radio Research Station, Slough, during transits occurring at about 1322 hr., 1510 hr., 1938 hr. and 2113 hr. U.T. on August 19. Signals from the satellite were also received at the Radio Research Substation, Singapore, at about 0800 hr. U.T. on August 20, but were not received at Slough later that day when the satellite was next due to be in the neighbourhood of Great Britain. This was explained by a *Tass* report of August 21, in which it was reported that the space capsule was brought out of orbit from a height of about 300 km. soon after 1200 hr. U.T. on August 20, having performed 18 revolutions.

Effects of Autonomy on Science and Technology

UNDER the somewhat misleading title "Local Self-Government", Political and Economic Planning has issued an admirable objective analysis of the experience of such regions of the United Kingdom as Wales, Scotland and Northern Ireland, and also the Isle of Man and of the Channel Islands (Vol. 26, No. 444 (12th September, 1960). Pp. 229-280. (London: Political and Economic Planning, 1960.) 5s.). That such an impartial account of the varying degrees of independence and interdependence of the governments of these territories and assessment of the present position scarcely touches on scientific matters as such in itself points to the spurious character of some of the claims for separate national scientific institutions or departments, and although the conclusions drawn touch only on the political and administrative aspects of autonomy, the broadsheet provides a reasoned and impartial appraisal of the arguments for and against autonomy, and of the difficulties and advantages that may well be of service to the scientist or technologist confronted with such claims. It is a real contribution both to the understanding of the present situation and to clear thinking about the real issues involved. The arrangements described are complicated, but it is clear that they are understood by interested and informed opinion in the territories concerned and that while the measure of autonomy enjoyed is varied, it is what it purports to be.

Survey of Information/Library Units in Industrial and Commercial Organizations

THE results of a survey of the information/library units of some 52 British industrial and commercial

R 322

organizations made in 1956-58 by Dr. D. J. Campbell are analysed in a report by Mr. C. W. Hanson, now published by the Association of Special Libraries and Information Bureaux (Pp. vi+42+vi. London: Aslib, 1960. 12s. 6d.; Aslib members 10s.). The survey was undertaken to provide factual data on the size, scope, organization, methods and cost of such units in the United Kingdom and it is based on a 12 per cent sample. Two-thirds of the units surveyed were responsible to a head of research or to a director, the remainder mostly to a senior technical officer. In terms of employees or staff the smaller organizations had relatively larger units than the larger organizations; the number of people served per information/library worker averaged 54, ranging from less than 20 to 200. 58 per cent of the heads of units were either graduates or chartered librarians or both. There were more men than women heads, but more of the women were qualified, and among the supporting staff there were three women to one man. Salaries and wages of staff accounted for about three times as much as the purchase of documents. Accommodation averaged 200 sq. ft. per member of information/library staff, but two-thirds of the organizations outside of London exceeded this figure. Two-thirds of the organizations took between 100 and 300 periodicals, the median number being 210, and one in twelve was in a foreign language; 16 per cent were later bound and 25 per cent were kept indefinitely unbound. Data on books were insufficient to permit any deductions, and only 6 out of the 52 units were responsible for the present organization's technical correspondence files. About half the units scanned national or local newspapers; 37 per cent possessed a microfilm reader and 8 per cent a microcard reader. About half used the Universal Decimal Classification, the rest using their own schemes. The main catalogue of 35 units comprised a classified index on cards; only one used a punched card subject index. Documents borrowed from outside libraries for 27 of the units averaged 12 per cent of the number lent from their own stock. About half did little or no stocktaking, and 48 units employed 23 different methods for recording loans. Only one-third could report how many inquiries they handled, but 90 per cent issued some kind of serial publication, commonly lists of new books and selected literature references, with abstracts.

Kirkia: a New Herbarium Journal

THE aim of *Kirkia*, the new journal of the Federal Herbarium, Salisbury, Rhodesia and Nyasaland (editor, H. Wild. From the Government Printer, P.O. Box 8062, Causeway, Salisbury. £1 10s. per annum), is to provide botanists in these regions, and elsewhere, with a readily available source of taxonomic information on a floristic region of very considerable interest; and to afford a medium for relevant botanical publications. To quote: "With regard to the aims of the journal our intention is to confine ourselves to articles concerning African botany and to give priority to articles dealing with taxonomy, floristic studies, phytogeography and the history of botany and botanical exploration which have some bearing on the flora of the Federation. Ecological articles may be published but usually only if they are of a general nature. As space permits we will welcome articles on these subjects relating to other African territories and particularly those territories which are our near neighbours". The name chosen for the

new journal commemorates the work of Sir John Kirk (1832-1922), who, as botanist, accompanied Livingstone to the Zambesi, Victoria Falls, Lake Nyasa, etc.

Museum of Comparative Zoology, Harvard

THE annual report for 1957-58 of the Director of the Museum of Comparative Zoology at Harvard College records progress in its usual activities of research, instruction to graduate students and curatorial routine (Pp. 28. Cambridge, Mass.: Museum of Comparative Zoology at Harvard College, 1960). The year was also marked by rather unusual activities such as expeditions by members of the staff to Asia, Australia and South America. Especially noteworthy of mention was a substantial grant from the National Science Foundation for the improvement of the collections and other facilities. The grant is to be spent over a five-year period and much of it will be used on scientific and technical assistance to bring the collections into good shape. Microscopes, other types of equipment and badly needed storage cases were also purchased. The report concludes with an impressive list of publications.

The National Museums of Southern Rhodesia

THE chief item of interest in the annual report for 1959 of the three museums which comprise the National Museums of Southern Rhodesia is an account of the handing over of the Umtali Museum. This was previously owned by the Umtali Museum Society, but is now administered by the Trustees of the National Museums of Southern Rhodesia. The Municipality of Umtali has allocated a one-acre site to house the material collected by the Society and also made a generous grant. The staff has been re-organized so that the Director of the Museums is now relieved of detailed administration of any one Museum and can devote his energies to overall planning.

New Electronic Teaching Apparatus

THE Griffin-Clarke-Smith electronic teaching apparatus 'Mechtronics' is a set of apparatus designed for easy assembly by pupils. A minimum amount of manual and technical skill is demanded of the user, since soldered joints are eliminated and the assemblies are screwed or clipped together on a peg-board layout. The complete set contains radio valves, transistors, a photoelectric device, and other electrical components. For qualitative experiments batteries only are required. For quantitative experiments external instruments are required together with suitable power supplies. The 'Mechtronics' set covers the requirements of the revised syllabus for the General Certificate of Education at Ordinary and Advanced Levels, and may be used by the enthusiast for a wide range of other electronics experiments. The apparatus is obtainable from Griffin and George, Ltd., Ealing Road, Alperton, Middlesex.

American Palms Illustrated

THE Chicago Field Museum of Natural History, which has issued many admirable volumes on the flora of Central and South America, including B. E. Dahlgren's "Index of American Palms" (14, Bot. Ser., pp. 438; 1936), has now produced a companion volume of palm illustrations (Dahlgren, B. E., 14, 412 plates; 1959. 10 dollars). These consist of

photographs of type specimens and of hitherto unpublished plates of Liebmann's elegant drawings, each with its appropriate references and annotations. This handsome volume should be of great value to workers in systematic botany remote from herbarium resources.

Geochemical Landscape

A 'GEOCHEMICAL landscape' is a term introduced by B. B. Polynov for a geochemical characterization of a given part of the Earth, as based on a joint influence of climate, relief, geological structure and vegetation, on the chemical processes occurring in this region and especially on the prevalent chemical elements and of their migration and accumulation. A. I. Perelman (*Priroda*, 3, 23; 1960) emphasizes that the main geochemical features of a geochemical landscape are determined by the biological cycle, although there are geochemical landscapes, like those of the polar or desert type, which are more or less abiogenic. For a brief characterization of a geochemical landscape, Perelman proposes a special geochemical formula, giving first the typomorphic elements and then, above the bar the element deficient and, below the bar the elements in excess of the average. The author emphasizes the importance of the study of geochemical landscapes for agriculture, the study of ore deposits and population health. A map in colour to the scale 250 km. = 1 cm. of the geochemical landscapes of the Soviet Union is given.

Medicinal Plants of the Arid Zones

UNDER this title a new investigation has recently been published under the auspices of Unesco ("Arid Zone Research." Pp. 13. H.M. Stationery Office, June 1960. 15s.). It will be noted that some twelve volumes in the Unesco Arid Zone Research Series have already been issued. These include digests of research on major topics such as plant ecology, hydrology, etc., and also monographs on particular subjects. In the present publication, which is of interest both to botanists and pharmacologists, indications are given of the directions in which research on medicinal plants is tending and of the economic possibilities which the utilization of such plants may afford. Dr. I. C. Chopra, of the Drug Research Laboratory, Jammu, India, has been primarily responsible for the botanical aspects, and Prof. R. Paris, of the Faculté de Pharmacie, Paris, for pharmacological aspects. The monograph contains a list of medicinal plants found in the arid zones. In the botanical section, following some general introductory matter, the genera and species of interest in pharmacy are set out alphabetically, briefly described, and their special properties and the relevant literature indicated. In the pharmacological section, the therapeutic or other commercial properties of the species are indicated, together with notes on local usage, artificial synthesis and the scope for further work on, and utilization of, the natural product. Some species possessing medicinal properties, on which no scientific work has yet been done, are mentioned. This section not only contains many items of considerable interest, but also affords a valuable brief survey of an extensive field of traditional and contemporary knowledge.

Eichhornia crassipes

H. R. J. DAVIES (*Nature*, 184, 1085; 1959) and N. W. Pirie (*Nature*, 185, 116; 1960) suggest that

the danger of the presence of *Eichhornia crassipes* in the Nile is over-rated, that uses might be found for the plant, and that research should therefore be concentrated in that direction rather than merely on the problem of its eradication.

A meeting was organized by the Scientific Council for Africa South of the Sahara in Leopoldville in 1957 to consider problems related to the spreading of this weed. This meeting was attended by specialists from Belgium, France and the United Kingdom, and was presided over by Prof. J. Lebrun, secretary-general of the Institut National d'Etudes Agronomiques au Congo and vice-president of the Scientific Council for Africa South of the Sahara, who is well known for his work in the field of tropical botany. The agenda of this meeting covered the following topics: biology and ecology of *Eichhornia crassipes* in tropical Africa; its effect on natural plant communities and other organisms; results of direct control measures; means applied to achieve control; effects of treatment on natural vegetation and on riverine crops; treatment in relation to climatic or hydrological conditions; utilization of *Eichhornia crassipes*; measures to be taken to avoid invasion by other aquatic pests. The recommendations made by this meeting (*Eichhornia crassipes*, CCTA/CSA Publication No. 27; PMB 2359, Lagos, B.P. 949, Bukavu) have served as the basis of the action undertaken by the Member Governments of the Commission for Technical Co-operation in Africa South of the Sahara in this field. That referring to the possible utilization of *Eichhornia crassipes* states: "The Symposium, bearing in mind that considerable research work and a number of experiments have been carried out in all countries affected by this pest, considers that there is no need to pursue such experiments. It draws attention to the danger of the dissemination of seeds by cattle food and composts produced from *Eichhornia*".

Leaf-Shape in Hybrids

IN a metrical study of leaf-shape in some *F*₁ hybrids and their parents, R. Melville has examined the proposition that the leaves of hybrids tend to be intermediate between those of their parents (*Kew Bull.*, 14, No. 1, 88; 1960). Leaves from four genera, *Forsythia*, *Prunus*, *Rhododendron* and *Ribes*, were investigated, with the following results. No exact intermediates were found in which the hybrid interaction was uncomplicated with some other phenomenon. The simplest type of interaction was an intergrading of characters along the leaf-axis, one parent being partially dominant towards the leaf-base and the other towards the apex, as in *Prunus* × *fontanesiana*. The parental effects were equally balanced in the *Rhododendron* hybrid, but there was positive heterosis on the character of relative leaf-breadth. In the *Ribes* hybrid axial intergrading was complicated by negative heterosis on the lengths of the large basal lobes of the leaf and positive heterosis on the breadths of the subterminal lobes. The *Forsythia* hybrid was found to have a leaf-shape exactly intermediate between the leaves of the simple leaved parent and the terminal leaflets of the other parent which had both simple and trifoliate leaves.

Experiments on Polarity in Flax Buds

H. F. GULLINE has investigated experimentally the polar development in adventitious buds of flax (*Linum usitatissimum*) and their associated vascular

system in hypocotyls (*Aust. J. Bot.*, 8, 1; 1960). Buds were induced on portions of epidermal tissue grafted in inverted positions on hypocotyls, and on hypocotyls subjected to reversal of the direction of gravity and electric polarity normally acting on them. The effects of experimental incisions into adventitious meristems, and in close proximity to them, were also studied. The basic pattern of development remained constant under all treatments. These experiments show that the epidermal and cortical cells from which the adventitious buds and their dependent vascular traces develop possess a very strong inherent polarity which could not be varied by extracellular changes of field.

Roosting Preferences of a Whiskered Bat

INVESTIGATIONS by Lord Cranbrook, and outlined in a recent issue of the *Transactions of the Suffolk Naturalists Society* (2, Part 4), have shown that a whiskered bat, given the opportunity of roosting in a vertical crevice, a horizontal crevice, a bare wall or hanging freely from the roof, showed a strong preference for the first. In a crevice of varying widths, it chose a place where the tips of the hairs on its back just touched the surface behind it, and it did not appear to mind whether it roosted in darkness or light; touch seemed to be the deciding factor.

Popular Culture and Personal Responsibility

THE National Union of Teachers is organizing a conference entitled "Popular Culture and Personal Responsibility", which is to be held at Church House, Westminster, London, S.W.1, during October 26-28. The conference has been divided into eight sessions, including such topics as the growth of communications in modern society, moral and cultural standards, the effects of mass media (with particular reference to young people), how the mass media are being used, the responsibility of the provider, the restrictions of working in the media, and the approach and attitude to the mass media. Further information can be obtained from the Public Relations Department, National Union of Teachers, Hamilton House, Mabledon Place, London, W.C.1.

University News:

London

DR. J. S. ROWLINSON, senior lecturer in the University of Manchester, has been appointed to the University chair of chemical technology tenable at the Imperial College of Science and Technology.

Among those appointed to readerships are: Dr. R. J. Goldacre (cell physiology), tenable at the Institute of Cancer Research, Royal Cancer Hospital; Mr. M. J. Way, at present principal scientific officer at Rothamsted Experimental Station (applied entomology), tenable at the Imperial College of Science and Technology.

College of Aeronautics, Cranfield

AMONG the recent appointments to lectureships at the College of Aeronautics are Mr. A. Rothwell (aircraft design) and Dr. A. C. Smith (mathematics).

Announcements

MR. H. STANESBY has been appointed deputy director of research at the General Post Office. He is at present staff engineer in the Radio Planning and

Provision Branch of the General Post Office Engineering Department. Mr. Stanesby has been closely connected with the work of the Institution of Electrical Engineers, and was chairman of the Radio and Telecommunications Section in 1955-56. In 1953 he was awarded the Insignia Award for Technology of the City and Guilds of London for his work in telecommunications.

DR. D. C. GARRATT has been elected chairman of the British Pharmaceutical Conference for 1960-61 and will preside at the meeting of the Conference to be held in Portsmouth during the week beginning September 18, 1961. Dr. Garratt is chief analyst to Boots Pure Drug Co., Ltd., Nottingham; he is also a vice-president of the council of the Society for Analytical Chemistry, and is chairman of its Analytical Methods Committee.

THE Palaeontographical Society has appointed Messrs. Bailey Bros. and Swinfen as distributing agents for its publications; inquiries about these publications should be sent to Bailey Bros. and Swinfen, Ltd., Hyde House, West Central Street, London, W.C.1.

THE Department of Chemical Technology of the Bradford Institute of Technology is holding a special short course on "Recent Developments in Plastics and Polymer Chemistry" during October 28-29. Further information can be obtained from Dr. W. R. Moore, Department of Chemical Technology, Bradford Institute of Technology, Bradford, 7. The fee for the course is £2 5s. 0d.

THE American Association for the Advancement of Science will sponsor a symposium on the Sciences in Communist China during its annual meeting in New York City on December 26-27, under a grant from the National Science Foundation. Preliminary plans call for review papers delivered by eminent American and international specialists on Communist China. Publication of these papers as a monograph is contemplated for the spring of 1961.

PROF. A. R. UBELLOHDE (Imperial College of Science and Technology) will deliver the fifth Charles Tennant Memorial Lecture entitled "Melting and Freezing" in the Royal College of Science and Technology, George Street, Glasgow, on November 4. Further information can be obtained from the Society of Chemical Industry, 14 Belgrave Square, London, S.W.1.

THE sixth congress on Theoretical and Applied Mechanics and a symposium on High Speed Computation Methods and Machines are being organized by the Indian Society of Theoretical and Applied Mechanics at the University of Delhi during December 23-26. The symposium is being jointly sponsored with the IBM International. Persons wishing to be present at either or both functions should contact Dr. B. R. Seth, Indian Institute of Technology, Kharagpur, India, from whom further information can also be obtained.

ERRATA. In the article entitled "Evolution of Nuclear Power Plant Design", by Sir Christopher Hinton, in *Nature* of September 24, on p. 1065, col. 2, line 13, the size of uranium rods is wrongly given as 17 in. in diameter; this should be 1 in.; on p. 1067, col. 2, par. 3, line 5, for "reaction" read "reactor".

THE AGRICULTURAL RESEARCH COUNCIL

IN 1958-59 the Agricultural Research Council administered a grant in aid of more than £4 million. Most of this money has been used for established research programmes, since less than half a million pounds was allocated to capital expenditure such as new buildings and the purchase of special equipment. The large expansion programme, embarked on soon after the War, which resulted in the establishment of a number of new institutes as well as extensions to existing institutes, now appears to be nearing its end. There is still one major gap in the field to be covered, and this is referred to in the recent report*, namely, a meat research institute; for which there is a very urgent need. Meat in all its forms is the most valuable commodity coming off British farms, and evaluation of quality is still a very subjective process. We have no thoroughly reliable basis for meat-grading schemes, and there is no real definition of meat quality to provide standards for selection work. Performance and progeny testing of carcass animals is in urgent need of such standards. It is to be hoped that there will be no further delay in the setting up of this institute.

Altogether there are reports from more than forty institutes and research units which are wholly or partly financed by the Council. At one end of the scale there are the giants like Rothamsted with ninety names on the professional staff list, and at the other there are the research units, usually centred at a university, with as few as three or four people working under the direction of a member of the university whose initiative and academic ability have earned the reward of such assistance.

Such units have a continuity usually determined by the duration of the director's university appointment, but this does not generally apply to the special grants which the Council makes to universities, colleges and similar organizations. These are normally limited to three years. A perusal of the list of projects suggests that it is not feasible to organize and complete many of these research tasks in a period so short as three years. Naturally the Council has to safeguard its funds, but it is very important for it to remember that university research cannot prosper if it is on a hand-to-mouth basis so far as finance and personnel are concerned. The quality of the staff the Council recruits, especially in respect of

graduates in basic sciences who are in demand from other industries, will depend very much on the kind of research that is being undertaken in the departments that train these recruits. This problem is likely to be aggravated as the 'bulge' descends on the universities, to reduce even further the opportunities university teachers have for personal research.

The reports from the individual institutes are brief and give little information beyond the range of the work that is being undertaken. One cannot, therefore, judge the emphasis that is being placed on the various lines, or estimate the progress that is being made. By way of compensation there are some excellent reviews on several aspects of research in Great Britain along the lines followed in the previous year's report. Because these reviews have a perspective, they are really more valuable than the strictly factual routine report. An outstanding review is that covering foot-and-mouth disease. One sees that the scope of the work being undertaken at the Pirbright Institute has very much more than local implications, and illustrates very effectively the importance of the Council's work to the world at large.

Following the same line of thought, it is heartening to see a reference to the secondment of research workers to countries which have recently achieved self-government, in order to fill the scientific gap created by the retirement of expatriate staff. Countries like Ghana and the Sudan urgently need help, and they are unlikely to obtain it by offering short-term contracts, for there is no certainty that the appointee will get suitable employment when the contract terminates. If, however, he knows that his post is open for him on his return, and that a colleague will replace him abroad to maintain the continuity of his work, then a very different atmosphere is created.

Unfortunately, if we in Britain do not provide this help it will be obtained from other countries, to the detriment of our relations with the emergent countries. This is well evidenced by what is happening in the Sudan. The need for this help exists not only in research but also in teaching, especially at the university level, and also in the provision of technical assistance. It is to be hoped that these initial steps are the fore-runner to a more comprehensive scheme of assistance to countries that need our help.

M. McG. COOPER

THE BACTERIAL GENERA *PSEUDOMONAS* AND *ACHROMOBACTER*

THE summer conference of the Society for Applied Bacteriology was held at the University College of North Wales, Bangor, during July 5-7. A paper-reading session occupied the first day, the last two days being devoted to a symposium on "*Pseudomonas/Achromobacter*".

The contributions to this session covered a wide field of both fundamental and applied problems concerning these two groups of bacteria, but the

themes which recurred and which promoted most discussion were differentiation and classification. As interests varied widely from the bacterial flora of meat, eggs, fish, water and soil to human and plant diseases, there were wide contrasts of approach and this led to useful exchanges of ideas.

In an introduction to the symposium, Dr. M. Ingram (Low Temperature Research Station, Cambridge) traced the history of the two genera through

the various editions of Bergey's "Manual of Determinative Bacteriology". He showed how over the years there has been a change of emphasis with regard to the importance of flagellation and pigmentation in the definitions of *Pseudomonas* and *Achromobacter*. Some species previously included in the latter genus have now been transferred to the former because of their polar flagellation; previously they had been excluded from the genus *Pseudomonas* because they showed no evidence of pigmentation. Even now that these two genera have been more clearly defined, reconsideration of the placing of some species seems called for. Dr. Ingram made it clear that he in no way wished to decry the value of the "Manual", and this point was later taken up in discussion when the meeting was reminded that the value of the contents of Bergey's "Manual" depends on the standard of work of the bacteriologists whose published descriptions of bacteria are included in it.

Dr. J. M. Shewan (Torry Research Station, Aberdeen) followed with an account of the methods used in his laboratory for the differentiation and classification of the Gram-negative rods associated with fish and for the broad grouping of *Pseudomonas* isolates. For initial separation, these methods depend on the following tests: colony form, pigment production, Gram's stain, motility and morphology (using phase-contrast microscopy), mode of insertion of flagella, antibiotic sensitivity, the oxidase test (Kovacs' method) and metabolism of glucose (Hugh and Leifson's test). *Pseudomonas* isolates are thus divided into three groups. Group I produce a soluble green pigment, oxidize glucose with the production of 2-keto acid and are generally resistant to terramycin. Group II are non-pigmented, oxidize glucose but are usually sensitive to terramycin. Group III are also non-pigmented but fail to oxidize glucose, giving a negative or alkaline reaction in Hugh and Leifson's test. Gram-negative coccoid rods which are non-motile and non-pigmented are classified as *Achromobacter* or *Alcaligenes* according to whether or not they oxidize glucose, while peritrichous rods are classed as Enterobacteriaceae. Other Gram-negative rods recognized are: *Vibrio*, *Aeromonas*, *Flavobacterium* and *Cytophaga*.

Basically the same procedure is being followed at the Low Temperature Research Station, Cambridge, for the examination of isolates from chilled poultry; in addition, they have found the arginine test useful for distinguishing *Pseudomonas* species from *Achromobacter*.

Prof. J. C. Ayres (Food Technology, Iowa State University) has employed further tests for the differentiation of *Pseudomonas* species isolated from poultry, meat and eggs, namely: growth temperature, gelatin liquefaction, fat hydrolysis, nitrate reduction and citrate and carbohydrate utilization. He groups *Pseudomonas* isolates according to whether they resemble *Ps. fluorescens*, *Ps. geniculata*, or *Ps. fragi*.

For isolates from soil, Dr. A. J. Holding (Edinburgh School of Agriculture) has used a similar range of tests; but he has found that litmus milk reactions and nitrogen utilization tests give useful additional information. Unlike workers in the fish and poultry fields, he classes as *Achromobacter* organisms which are motile and predominantly rod-shaped.

A note of caution was sounded by Dr. K. Klinge (Hygienischbakteriologisches Institut, University of Erlangen) in connexion with undue reliance being placed on individual biochemical tests. He instanced

the oxidase test where, using Graby and Hadley's method, he found that the number of strains of *Ps. aeruginosa* giving a positive reaction depend on the medium in which they are grown. A yeast extract medium has proved the most favourable.

Dr. A. M. Paton (Department of Bacteriology, Aberdeen) described media that can be used in the isolation and identification of plant pathogenic bacteria. He has found that a gluconate basal broth is semi-selective and is a useful enrichment medium prior to plating on nutrient agar and 5 per cent sucrose agar. With regard to the latter medium, it is important to realize that production of levan from sucrose is not restricted to certain plant pathogens but is characteristic also of some saprophytic pseudomonads associated with plants. Other tests for identification of plant pathogens suggested by workers in this field were, phage sensitivity and the ability to produce poly- β -hydroxy-butyric acid, a sudanophilic substance, which is characteristic of certain of the non-fermentative Gram-negative rods.

It was evident both from the main papers and from subsequent discussions that the approach of each worker to questions of differentiation and classification depended on the particular problems encountered in his own field. Some, notably those concerned with fish and flesh, wanted at an early stage to be able to separate the non-pigmented *Pseudomonas* from *Achromobacter*. Dr. Holding indicated a further difficulty with soil isolates; saprophytic *Xanthomonas* strains which have lost their ability to form pigment appear to be indistinguishable from the non-pigmented *Pseudomonas*. In contrast to the workers in the above fields, the medical bacteriologists required tests for the rapid detection of *Ps. aeruginosa* and of relatively few other non-fermentative Gram-negative rods. Dr. Klinge described tests he had used to distinguish *Ps. putida* and *Ps. fluorescens* from *Ps. aeruginosa* and also mentioned *Bacterium anti-tratum*, which he and some other workers have suggested should be included in the genus *Achromobacter* (this view has been questioned by others). For Dr. K. B. Rogers (Children's Hospital, Birmingham), speed of diagnosis is an urgent necessity, and his aim is to find a means of recognizing *Ps. aeruginosa* within 12 hr. of culturing. Plant bacteriologists also were seeking means of distinguishing the pathogenic from the saprophytic *Pseudomonas* within a reasonable period.

Although differentiation on the basis of a few tests was the primary task of most, many were deeply concerned with the classification of their isolates. Several speakers made a plea that the two should not be confused, though it was recognized that what proved to be a useful scheme for differentiation might also be a logical basis for classification. None appeared entirely satisfied with the present position regarding the two genera, *Pseudomonas* and *Achromobacter*, but there was no move to make drastic changes at this stage. The main need seemed to be for all named species to be very fully described and for them to be available in the culture collections. Prof. Ayres stressed the need for rigid standardization of the constituents of media and other factors such as temperature, age and size of inoculum and growth-medium when characterizing bacteria. He also pointed out that the present system of classification is based to a great extent on unstable characters. A number of workers, in the fields of fish, food and water bacteriology, have been using an electronic

computer to analyse their collected results, applying the theory that, in classification, every feature of an organism should be given equal weight. For this procedure, a minimum of 80 different features was quoted as necessary.

Apart from problems of differentiation and classification, considerable attention was paid to the ecology and development of *Pseudomonas* and *Achromobacter*. Workers at the Torrey Research Station have found that, while on fresh fish *Achromobacter* species are present in rather larger numbers than *Pseudomonas* species, after about 15 days on ice the latter become dominant. Many of them are dependent on sea-water and can multiply at 0° C. Similarly, it was found at the Low Temperature Research Station that non-pigmented *Pseudomonas* species become dominant on stored chilled poultry. They are associated with 'putrid' off-flavours compared with 'fruity' ones produced by *Achromobacter*. Prof. Ayres has also found that on raw flesh the dominant organisms are coccoid, motile, aerobic and non-pigmented. On eggs, he has encountered various *Alcaligenes* and *Pseudomonas* species, but only a small proportion can penetrate the inner membrane and cause spoilage. Dr. J. Brooks gave an account of factors which limit bacterial multiplication in egg-white; they included lysozyme, pH and the inavailability of protein and of iron, biotin and probably other trace elements. He has found that, so far as penetration of the egg membrane is concerned, age is an important factor, and by the twelfth day entry by infecting organisms is much more rapid.

A description of the distribution of Gram-negative organisms, including *Pseudomonas* species, in freshwater, by Miss Vera G. Collins (Freshwater Biological Association, Windermere) threw light on the importance of layering effects on the distribution of bacteria in lakes, while the final paper of the symposium, by Dr. Rogers, showed how a single species, *Ps. aeru-*

ginosa, could persist in and heavily infect surgical apparatus which could not be sterilized by heat. This organism proved highly resistant to the non-corrosive chemical disinfectants and the use of infected apparatus could lead to severe and even fatal infections in children. From the discussion which followed, it appeared that dairy cows have become more liable to infection by this organism in recent years.

Two remaining papers dealt with fundamental approaches to two distinct problems. The first was by Prof. J. de Ley (Microbiology Laboratory, State University, Ghent), who gave a clear and convincing account of the carbohydrate metabolism and localization of enzymes in micro-organisms related to *Pseudomonas*. During the discussion which followed, there was a plea that bacteriologists and the biochemists should work more closely together in the future. It was the feeling of several workers that knowledge of metabolic pathways is of fundamental importance in the classification of bacteria. In the second paper, Dr. A. M. Paton (Department of Bacteriology, Aberdeen), discussed the role of *Pseudomonas* in plant disease. He welcomed the recent increase in knowledge of the metabolism of members of this genus, though as yet the results referred to relatively few species and their general validity is still unknown. After referring to various fundamental problems concerning plant/*Pseudomonas* relationships, he went on to describe the use of plant tissues embedded in nutrient agar for the investigation of pathogenicity mechanisms. He thought that, until more is known of such mechanisms, progress in plant disease control will be limited.

The papers read at the symposium and also contributions to the discussion on "Methods of Isolation and Differential Techniques" will be published in full in the *Journal of Applied Bacteriology*.

EVE BILLING

PHYSIOLOGY OF THE BANANA PLANT

COMPREHENSIVE investigations of the physiology of the banana plant are now being undertaken by Prof. F. C. Steward and colleagues in Cornell University. Of the three parts which have now appeared (*Ann. Bot.*, N.S., 24, 83, 117, 147; 1960) Part 1 deals with the detection and estimation of biochemical substances in the banana plant, in particular, the nitrogenous constituents of alcohol-soluble extracts, and keto-acids and non-volatile organic acids. The classes of nitrogen compounds to which attention is given are the amino-acids and their amides, certain volatile amines, ureido and guanido compounds, and certain indole compounds. In view of the large amount present in fruit of the Gros Michel variety, free histidine was isolated and critically identified. The use of various reagents and tests for these various classes of substances on paper chromatograms are described.

The range of substances which have been detected by these means in the banana leaf, leaf-sheath, fruit (pulp and peel) and stem exudate is shown by their location on paper chromatograms. Evidence is presented which indicates qualitatively the degree of prominence of the different substances in the tissues or extracts which have been examined.

Part 2 relates to factors which affect the nitrogen compounds of the fruit of several varieties subsequent to harvesting. In Gros Michel from Honduras, the amides (asparagine and glutamine) and histidine are of special importance in the soluble nitrogen fraction of the fruit. Prominent changes occur in the nitrogen compounds as the fruit ripens, and these are shown to be markedly influenced by the conditions that obtain during the development of the fruit. The nitrogenous composition of the fruit (Gros Michel) is markedly affected by the season of the year at which it forms; this affects the balance between the amides (asparagine and glutamine) and histidine, and also influences the post-harvest metabolic behaviour in ways which are described. While the total protein of the fruit is relatively stable in its amino-acid composition, certain differences were noted which seem to characterize the Gros Michel as it grows in Central America, and some shifts in the amino-acid balance in the protein seem to occur with ripening. It was also ascertained that the very young inflorescence is at first relatively rich in soluble nitrogen compounds.

After the early phase of growth, involving cell division, has elapsed, the fruit utilizes its soluble

nitrogen in synthesis faster than it is supplied to the fruit, so the soluble nitrogen complement falls to a low level; thereafter it increases again to a new higher level at harvest. The composition of the soluble nitrogen fraction as stored at harvest is quite different from that which obtains in the inflorescence in which the fruit is being initiated. The latter emphasizes the amides (asparagine and glutamine) and histidine; the former emphasizes alanine and glutamine as the only prominent amide.

In Part 3, nitrogen compounds of the leaves are considered. The materials analysed were obtained from plants grown in sand cultures either supplied with full nutrient solution or with solutions deficient in each of the several major nutrient elements. The growth was continued long enough to establish the conditions characteristic of these nutrient treatments. Extracts of leaves, sampled according to their position on the axis, have been made from plants grown in

full nutrient solution; these extracts have been examined by chromatographic methods to detect and determine the various nitrogen compounds they contain.

The relative proportions of the soluble nitrogen compounds of the banana leaf are quite different from those of the fruit and, in response to the deficiency of specified mineral nutrients, both the total amount and the relative composition of the soluble nitrogen fraction are greatly affected. The results are interpreted in terms of the more active accumulation of soluble compounds in young leaves and the maintenance of a low amide (glutamine)-level in leaves engaged in protein synthesis. The accumulation of soluble nitrogen compounds when growth and synthesis are arrested, and the relative accumulation of a specified number of nitrogenous substances, due to the lack of a nutrient element, indicate that metabolic blocks in reaction pathways occur.

THE NUCLEUS OF THE ANDROMEDA NEBULA

IN 1959 the electronic camera developed by Lallemand and Duchesne in Paris was taken to the Lick Observatory on Mount Hamilton, California, and installed at the focus of the coude spectrograph of the 120-in. reflector. Among the objects chosen for observation was the nucleus of the Great Nebula in Andromeda, *M* 31. The nucleus appeared on the slit as almost stellar, the inner parts of the nebula which are normally so conspicuous on photographs being invisible.

The results of the observations have been reported by A. Lallemand, M. Duchesne and M. F. Walker (*Pub. Astron. Soc. Pacific*, 72, 76; 1960). The first spectrogram of the nucleus was made in very good seeing when a stellar image was about half a second of arc in diameter, and the image of the nucleus was of diameter 4.4". It showed at once that the *H* and *K* lines of Ca II, which were the only ones clearly visible, were markedly inclined through the nucleus. Subsequent observations confirmed this. The observations have been interpreted on the assumption that the inclination of the lines is produced by the rotation of the nucleus, and, when converted to the equivalent velocities in circular orbits, the measures yield a maximum circular velocity of 87 km./sec. at a distance of 2.2" from the centre of the nucleus.

Beyond this distance the velocity appears to decrease, a velocity of 42 km./sec. being measured at 4.2" from the centre.

Previous observations of the rotation of *M* 31 refer to points farther from the centre, the innermost point being at 25" from the centre. The velocity apparently has a minimum somewhere in the region of 10" from the centre, a maximum at 3", another minimum at 9", and an increasing velocity for greater distances. If one assumes that the nucleus is spherical, of radius 2.2', and that it rotates as a solid body with a maximum circular velocity of 87 km./sec., its properties may be calculated. Its radius is 7.4 parsecs, its mass 1.3×10^7 solar masses, its average density 1.5×10^3 solar masses per cubic parsec and its rotation period 5.2×10^6 years. Its mass-to-luminosity ratio is about 3.6 in solar units. The nucleus is therefore similar in size to a giant globular cluster, but one hundred times more massive and twenty times as dense and as luminous. It rotates one to two orders of magnitude faster than the rest of *M* 31. The results indicate that the nucleus is a separate dynamical entity, although spectroscopic evidence suggests that its stellar composition is like that of the surrounding central regions.

RESULTS OF THE OCCULTATION OF REGULUS BY VENUS, JULY 7, 1959

By DR. G. de VAUCOULEURS and DR. D. H. MENZEL
Harvard College Observatory, Cambridge, Mass.

1. Ingress and Egress Observations

TABLE 1 gives the times T_1 , T_2 of the half-intensity phase, $\Delta m = 0.75$ mag., at ingress and egress derived from visual, photographic and photoelectric observations secured by members of the Harvard College Observatory (stations 1a, 2, 3, 4, 5,

7) and Smithsonian Astrophysical Observatory (stations 1b, 6) expeditions. Rain and clouds prevented observations at two other stations (Castel Gandolfo, Asiago). Additional observations (stations 8-24) were received by letter or taken from published sources. Station co-ordinates, observers and sources are listed in Table 2. Published observations

at more than twenty other stations were found to discordant or incomplete for inclusion in the final solution. The 'observed' times in Table 1, when derived from visual observations, are interpolated to $\Delta m = 0.75$ mag. with the help of the theoretical light curve derived from the photoelectric observations of ingress at stations 2 and 7 and are corrected where required for a personal equation of 0.2-0.3 sec. on the average.

2. Geometric Results

The observed mid-eclipse times $T_m = \frac{1}{2}(T_1 + T_2)$ and durations $D = T_2 - T_1$ were compared with the values computed from the apparent co-ordinates of Venus and of α Leonis ($\alpha = 10h. 06m. 12.193s.$, $\delta = +12^\circ 09' 56.424''$) derived from the American ephemeris data. The ephemeris radius and parallax of Venus were $R_V = 14.25''$, $R_E = 14.91''$ for a dis-

Fig. 1. Projection on plane tangent to celestial sphere of apparent motion of Regulus with respect to Venus. P_1, P_2 , apparent positions at 14h. 24m. and 14h. 36m. U.T. I , ingress; E , egress; M , mid-occultation point ($MV = r$). Dashed lines, geocentric paths

tance $\Delta = 0.59005$ A.U. ($\sigma_1 = 8.41''$, $\pi_0 = 8.80''$). The speed of the apparent motion of Venus was approximately $\dot{s} = 0.0339''$ per sec. of time in position angle $\theta = 118^\circ 37'$, the exact values varying slightly from station to station.

The mean $O-C$ for the mid-eclipse time from nineteen stations, $\Delta t = T_m$ (observed U.T.) - T_m (computed E.T.) = $-28.1s. \pm 0.2s.$, can be interpreted as a determination of Ephemeris Time from the motion of Venus in longitude. A provisional value for 1959.5 derived at the U.S. Naval Observatory from observations of the Moon is $\Delta t_1 = -32.4s.$ (Markowitz, W., personal communication). The 4.3 sec. difference between the two values is well within the possible errors in the star position and in the Venus ephemeris (several tenths of a second of arc).

If ΔR , Δr are the corrections to the ephemeris values of the radius of Venus R_s and of the minimum distance r_s between the star and the centre of the disk (Fig. 1), the difference $O-C$ between the observed and computed durations $D = T_2 - T_1$ is to the first order:

$$\dot{s}(D_o - D_c) \cos \beta_s = \Delta R - \Delta r \sin \beta_s \quad (1)$$

with $\sin \beta_s = r_s/R_s$. Starting from first-approximation values of ΔR , Δr determined graphically, a least-squares solution for sixteen stations leads to:

$$\Delta R = +0.150'' \pm 0.005'', \Delta r = +0.315'' \pm 0.010''$$

The corrections Δt and Δr when applied to the ephemeris data give the following values for the observed differential geocentric co-ordinates (α Leo - Venus) on July 7, 1959, at 14h. 24m. 00s. Universal Time:

$$\begin{aligned} \Delta \alpha \cos \delta &= +9.110'' \pm 0.010'' \\ \Delta \delta &= -0.334'' \pm 0.010'' \end{aligned}$$

The final $O-C$ of the ingress and egress times computed with these corrected co-ordinates and the observed planetary radius $R_o = R_s + \Delta R = 14.400''$ are listed in Table 1 and plotted in Fig. 2 as a function

* All errors quoted are p.e.

of $\sin \beta = r/R$. All residuals are less than $\pm 6s.$, except at ingress in station 22 (rejected), and at egress in station 4, where observation was interfered with by a thick haze; the average deviation for the other stations is $\pm 1.6s.$ at ingress ($n = 23$), $\pm 1.7s.$ at egress ($n = 18$). The mean $O-C$ is $-0.51s. \pm 0.22s.$ ($n = 23$) at ingress and $-0.36s. \pm 0.27s.$ ($n = 18$) at egress. However, the photoelectric light curves of ingress at Le Houga and Bloemfontein (section 3) give $(O-C)_1 = +0.4s. \pm 0.3s.$ and $+0.3s. \pm 0.4s.$, respectively, and the excellent visual observations at Pretoria $(O-C)_{1,2} = 0.0s. \pm 0.3s.$ No residual correction is indicated.

The observed radius $R_o = 14.400''$ does not refer to the cloud-level, but to a much higher level in the upper atmosphere where the differential refraction effect amounts to 0.75 mag. This radius must be further corrected for the total refraction $\omega_o = 0.016''$ at this level (section 3), since the observed durations are shortened by refraction (Fig. 3). The corresponding radius at unit distance then is:

$$\sigma_1(z_o) = (R_o + \omega_o) \times \Delta = 8.506'' \pm 0.003''$$

This value demonstrates that the numerous filar micrometer determinations of the semi-diameter of Venus in excess of $8.5''$ are in error; the best measurements with double-image micrometers during transits or with the filar micrometer on the narrow crescent phases give $\sigma_1 = 8.41'' \pm 0.01''$ in agreement with the ephemeris value. The altitude of the occulting shell (at half intensity) then is:

$$\sigma_1(z_o) - \sigma_1(z_c) = 0.096'' \pm 0.011''$$

Fig. 2. Residuals $O-C$ of ingress (●) and egress (○) times at half-intensity for corrected elements versus $\sin \beta = r/R$

or:

$$z_0 - z_c = 70 \pm 8 \text{ km.}$$

above the cloud-level.

3. Photometric Results

The fading phase of ingress at the dark limb was successfully observed photoelectrically at the Périquier Observatory, Le Houga, France (station 2), and at the Boyden Observatory, Bloemfontein, South Africa (station 7). The unsmoothed readings at 0.24-sec. intervals are compared in Figs. 4 and 5 with theoretical light curves computed from the classical theory of extinction by differential refraction in a homogeneous atmosphere^{1,2}. It was not found possible to fit the observations with a constant scale height $H = RT/mg$, that is, a homogeneous isothermal atmosphere; both curves indicate a small, but definite, increase of H with altitude. In the observable range $|z - z_0| < 20 \text{ km.}$, the scale height may be written:

$$H(z) = H(z_0) \left[1 + \frac{1}{H} \frac{\partial H}{\partial z} (z - z_0) \right]$$

Fig. 4. Photoelectric observations of ingress at the Périquier Observatory, Le Houga, France, compared with theoretical curve for adopted scale height. Inset: residuals, note damping of scintillation during fading phase

Fig. 5. Photoelectric observations of ingress at Boyden Observatory, Bloemfontein, South Africa, compared with theoretical light curve for adopted scale-height. Inset, residuals

with:

$$H(z_0) = 6.8 \pm 0.2 \text{ km.}$$

(corresponding to a total refraction angle $\omega_0 = H/\Delta = 0.0160''$) and:

$$\frac{1}{H} \frac{\partial H}{\partial z} = +0.010 \pm 0.002 \text{ km.}^{-1}$$

The residuals are shown in the insets; the variation of H with height, although small, seems real, since it was not possible to secure a satisfactory fit with a constant value. Note that because of the different geometry of the occultation in France ($\sec \beta = 1.38$) and in South Africa ($\sec \beta = 1.02$), the actual time-scales for fading are notably different in the two stations; the satisfactory fit of both curves by a single set of parameters is therefore a significant check.

With the acceleration of gravity $g(z_0) = 860 \text{ cm. sec.}^{-2}$, we have:

$$\frac{T}{m} = 1.03 H$$

or, for $H = H(z_0)$:

$$T(z_0) = 7.0 \bar{m}$$

For the plausible value $m = 42.5$, corresponding to the assumed volume composition carbon dioxide = 0.90, nitrogen = 0.09, argon + others = 0.01:

$$T(z_0) = 297 \pm 10^\circ \text{ K.}$$

(280° K. for nitrogen/carbon dioxide = 1, $m = 36$; 308° K. for nitrogen/carbon dioxide = 0, $m = 44$).

Further, if we assume that $\partial m / \partial z = 0$ (that is, no photodissociation of carbon dioxide or nitrogen in the range $z_0 \pm 20 \text{ km.}$), the value of $\partial H / \partial z$ implies:

$$\frac{\partial T}{\partial z} \simeq +3^\circ \text{ km.}^{-1}$$

or a range of variation from 240° K. near $z - z_0 = 50 \text{ km.}$ to 360° K. near $z - z_0 = 90 \text{ km.}$

The total pressure at altitude z_0 is:

$$p(z_0) = 2.6 \pm 0.13 \text{ dynes cm.}^{-2};$$

it is practically independent of the adopted mixing ratio nitrogen/carbon dioxide. The corresponding mass and reduced thickness above z_0 are:

$$m(z_0) = 3.0 \times 10^{-3} \text{ gm.}$$

$$h(z_0) = 1.7 \text{ cm. N.T.P.}$$

The reduced thickness of the atmosphere along the light path for the grazing ray at z_0 is:

$$X(z_0) = 1.3 \text{ m.}$$

Absorption effects by known or suspected atmospheric gases must therefore be entirely negligible and the observed light curve can be safely interpreted in terms of pure differential refraction effects.

Given the photometric curve for a central occultation (Fig. 6) and the corrected elements of section 2, it is easy to compute the magnitude loss $\Delta m = -2.5 \log I/I_0$ at the observed instants of disappearance T_D

T_D (or T_R), time when last seen at ingress (or first seen at egress), corrected for personal equation; $O-C$, observed T_D (or T_R) minus computed ingress (egress) times at half-intensity T_I (or T_E), Δm , magnitude difference read on standard light curve at time $t = T_I$ (or T_E) + $(O-C)/\text{sec } \beta$; $D-R$, $\Delta m_D - \Delta m_R$.

Station 2b: T_E , doubtful at 25.7s., definite at 28.8s. Station 8: T_E , doubtful at 25.5s., definite at 27.5s. Station 17: T_E , doubtful at 50.8s., definite at 53.8s. Station 12: T_D , ± 10 s. (clouds). Stations 3, 4, 6a, 12 (T_E), 13 (T_D), 16, 21: hazy sky.

and reappearance T_R (Table 3). At both ingress and egress the gain in Δm for large telescopes was only slight; on the average $\Delta m_D = -0.5 + 1.5 \log A$ at ingress, and $\Delta m_R = -1.4 + 1.5 \log A$ at egress, if A is the telescope aperture in cm. On the average, $\Delta m(D) - \Delta m(R) = +0.9$ mag., that is, the star was not detected at the bright limb until it was more than twice as bright as when last seen at the dark limb. For instruments in the range $A = 10$ –40 cm., $\Delta m_D \approx 1.5$ mag., $\Delta m_R \approx 0.6$ mag. with a dispersion $\sigma \approx \pm 0.3$ mag.; in stations with a bright, hazy sky $\Delta m_D \approx 0.5$ to 1.0 mag. and $\Delta m_R \approx 0.0$ (with T_R occasionally late by 5–10 sec. or more); in stations with good seeing and dark blue sky $\Delta m_D \approx 2.0$ to 2.5 mag.

4. Atmospheric Model

A tentative atmospheric model incorporating the occultation results is shown in Fig. 6. The schematic temperature curve is based on the following data:

(1) Surface temperature: $T(0) = 580^\circ \text{K.}$ (from micro-wave observations).

(2) Lower stratospheric temperature: $T(z^*) = 285^\circ \text{K.}$ (from spectroscopic observations) at an estimated altitude $z^* \approx (580 - 285)/10 = 29.5$ km. for an assumed mean adiabatic gradient $\Gamma = -10 \pm 1^\circ \text{K. per km.}$; according to Kuiper, the top of the cloud layer is about 0.46 H lower, hence $z_c \approx 27 \pm 5$ km.

(3) Upper stratospheric temperature: $T(z_r) = 235^\circ \text{K.}$ (from the radiometric observations) at an estimated altitude $z_r - z_c \approx 40$ –50 km. or $z_r \approx 65$ –75 km.

(4) Occultation-level temperature: $T(z_0) = 297^\circ \text{K.}$ at $z_0 - z_c \approx 70$ km. or $z_0 \approx 95$ –100 km.

With this temperature curve the mean temperature between z_0 and z_c is $\bar{T} = 260 \pm 10^\circ \text{K.}$ and the mean scale height $\bar{H} = 6.0 \pm 0.2$ km., so that:

$$\log p(z_0) - \log p(z_c) = (z_0 - z_c)/2.30 \bar{H} = (z_0 - z_c)/13.7$$

If we assume for the pressure at the top of the cloud layer the commonly accepted value $p(z_c) = (1.6 \pm 0.2) \times 10^5$ dyne cm.^{-2} , the observed pressure at the occultation-level $p(z_0) = (2.6 \pm 0.13)$ dyne cm.^{-2} implies an altitude difference:

$$z_0 - z_c = (5.20 - 0.41) \times 13.7 = 65.5 \pm 2.5 \text{ km.}$$

in good agreement with the observed value 70 ± 8 km. The pressure distribution $p(z)$ corresponding to the temperature curve and the adopted value of $p(z_c)$ is shown in Fig. 7. The surface pressure of the

Fig. 6. Standard light curve for central occultation ($\beta = 0$) on July 7, 1959, with $H(z_c) = 6.8$ km., $\partial H/\partial z = +0.01 H$

Fig. 7. Atmospheric model incorporating micro-wave, radiometric, spectroscopic and occultation data. Schematic temperature distribution (scale at top) and derived pressure curve for $p(z_0) = 160$ millibars at top of cloud layer ($z_0 \approx 27$ km.). The occultation pressure $p(z_0) = 2.6$ dyne cm^{-2} obtains at $z_0 = 65.5$ km, where $T(z_0) = 297^\circ \text{K}$.

model, $p_0 \approx 2.5$ atm., uncertain by a factor 2–3, is not directly relevant to the interpretation of the optical data.

If $\sigma_1(z_0) = 8.506'' \pm 0.003'' = 6,165 \pm 2$ km., $z_0 - z_c = 65 \pm 2.5$ km. and $z_c = 27 \pm 5$ km., the

optical semi-diameter of Venus then is $\sigma_1(z_0) = 8.506'' - 0.090'' = 8.416'' \pm 0.005'' = 6,100 \pm 4$ km. and the radius of the solid globe $\sigma_1(0) = 8.506'' - 0.127'' = 8.379'' \pm 0.008'' = 6,089 \pm 6$ km. $= 0.955 \pm 0.001$ ($\delta = 1$).

This investigation was supported by the Geophysics Research Directorate of the United States Air Force under Contract AF19(604)–3074 with Harvard University. The occultation expeditions of Harvard Observatory received additional support from the Boeing Airplane Company of Seattle. The Harvard and Smithsonian expeditions are, further, indebted to the Directors and staffs of Madrid Observatory, Páridier Observatory at Le Houga, Merate Observatory, Catania Observatory, Vatican Observatory at Castel Gandolfo, Asiago Observatory, American University Observatory in Beirut, and Boyden Observatory at Bloemfontein for their hospitality and co-operation. We thank also the many persons who communicated details of their observations by letter, and Mrs. A. de Vaucouleurs, who ably carried most of the computing load. All computations and reductions were checked twice. A full report will be published elsewhere.

VARIATION WITH TEMPERATURE OF YOUNG'S MODULUS OF POLYCRYSTALLINE GRAPHITE

By I. B. MASON and R. H. KNIBBS

U.K. Atomic Energy Authority Research Group, Atomic Energy Research Establishment, Harwell, Didcot, Berks

IT is well known that at $1,000^\circ \text{C}$. the elastic moduli of artificial graphites rise with temperature^{1,2}. It is also often assumed that this positive variation with temperature exists down to room temperature, although there appear to be no actual measurements to confirm this. Some fairly precise measurements of Young's modulus from 20° to $1,000^\circ \text{C}$. which we have made indicate that the variation with temperature is not always positive; there is, in fact, a well-defined minimum in the region of 200°C . This is a result of considerable importance in connexion with work on the structure of polycrystalline graphite artefacts, and is also of fundamental interest in indicating that the basic graphite crystallite probably exhibits a negative temperature coefficient of one or other of its elastic moduli, in conformity with most crystalline materials.

The only other evidence of a negative temperature coefficient for a carbon in this temperature-range appears to be that given by Davidson *et al.*³ for an artefact heat-treated to $1,400^\circ \text{C}$. They found a net negative variation of rigidity modulus between 0° and $1,000^\circ \text{C}$. and continuing up to $1,400^\circ \text{C}$., but with no indication of this variation becoming positive.

Representative results obtained in the present investigation are shown in Fig. 1. These relate to a nuclear reactor grade carbon stock, heat-treated to final temperatures of $1,200^\circ$, $2,100^\circ$ and $2,600^\circ \text{C}$. respectively. The modulus was measured in all cases in a direction parallel to the extrusion axis.

The measurements were made by an adaptation of the flexural vibration method first described by Forster⁴. The specimens, 4 in. long and $\frac{1}{8}$ in. diameter, were suspended horizontally in a platinum-wound mullite furnace tube by two graphitized cellulose threads connected respectively to the vibrator and the pick-up units. The vibrator was driven from a Muirhead decade oscillator and the resonance condition determined with a cathode-ray oscilloscope. The pick-up units were mounted on water-cooled supports and shielded from the furnace winding so as to keep their temperature below 50°C . The whole assembly was operated in a vacuum chamber at a pressure of 10^{-4} mm. mercury. The fundamental frequency ranged from about 800 to 2,000 c./s. for all the materials considered. The variation with temperature is relatively small, and at $1,000^\circ \text{C}$. the frequency can be as little as 50 cycles above the value at room temperature. In all cases specimens were given a preliminary degassing run to $1,000^\circ \text{C}$., under vacuum, before making measurements.

In addition to the pronounced minima, a noteworthy feature of these results is the hysteresis between heating and cooling (the direction of change of temperature is indicated in Fig. 1 by the arrows); this is, in general, more pronounced for the higher treatment temperatures. On re-cycling four or five times, the degree of hysteresis showed a tendency to diminish very slightly. Heating and cooling were

Fig. 1. Relative variation of Young's modulus as a function of temperature for Acheson reactor grade carbon (a) heat-treated to 1,200° C.; (b) heat-treated to 2,100° C.; (c) heat-treated to 2,600° C.

each normally carried out over a period of about 3 hr. It was observed that, if the temperature was held at some intermediate value during heating, the modulus would tend to rise toward the cooling curve. But the holding time has not yet been extended long enough (more than 19 hr.) actually to reach the 'cooling' condition. No such effect was observed on holding during cooling.

The temperature at which the minima occur is not constant but appears to lie between 100° and 300° C., depending on the nature of the material. As indicated above, the region of negative variation with temperature is of great interest, and experiments now in progress indicate that this extends down to a temperature of -196° C. It is considered that this behaviour reflects either the behaviour of the crystal shear modulus (G_{44}) or a dilatational modulus (G_{11} or C_{33}), all of which are expected to fall with rising temperature in accordance with general theory. The occurrence of a minimum and a subsequent rise of modulus may then be attributed to some structural change which becomes important at about 200° C.

There are two possible explanations of the positive variation with temperature, and both depend on the anisotropic nature of the graphite single crystal. The first, proposed by Mrozowski⁴, is that, on heating, internal cooling stresses introduced during manufacture (that is, on cooling from the final heat-treatment temperature) become relieved, with consequent increase in strength and modulus. The other, described by Hove⁵, is that, on heating, the large *c*-axis expansion of the crystallites, hitherto accommodated in the voids between the crystals, enables a filling-in of these voids to take place, thus tightening up the

structure; this, incidentally, allows the *c*-axis component to play an increasingly larger part in the artefact expansion as the temperature rises. At this stage it is possible to raise three objections to the first, or 'strain', hypothesis: (i) Present results indicate that any built-in strains would cease to be effective below 200° C. There is no obvious reason why this should be so. (ii) The time-dependent nature of the heating curve and the relative stability of the cooling curve suggest that annealing does go on at these temperatures, and hence that there would be little tendency for strains to build up during the much slower cooling conditions of manufacture. (iii) Greater strains (at room temperature) should be induced by the higher heat-treatment temperatures, thus resulting in steeper modulus variations. This is not in agreement with the experimental results.

Davidson and Losty⁶ have objected to the second, or 'void', hypothesis. They suggest that Wigner growth of the crystal resulting from neutron irradiation ought to be related to the consequent increase of modulus of the artefact in a manner parallel to the thermal case, whereas in fact it is found that under irradiation the modulus of the artefact increases far more rapidly than in the thermal case.

However, the present facts seem to favour the void hypothesis. On elementary grounds one would expect, on the basis of either hypothesis, accompanying changes in expansion coefficient. As already pointed out, the void hypothesis requires both the modulus and the expansion coefficient to change in the same sense. On the other hand, the strain hypothesis implies that modulus and expansion should change in opposite senses. For, in this case,

Fig. 2. Temperature variations of thermal expansion coefficient (a) and Young's modulus (*E*) as functions of heat-treatment temperature at ambient temperature of 600° C.

any increase in modulus must presumably arise from a net effective reduction in molecular spacing, and this would result in a fall in expansion coefficient. In Fig. 2 are shown, plotted together, the variations with temperature of modulus and expansion coefficient as functions of heat-treatment temperature. The modulus variations have been determined from the cooling curve and correspond to an ambient temperature of around 600° C. The expansion data were obtained by Mr. T. Beirne, using the push-rod-and-tube technique on $\frac{1}{4}$ -in. diameter specimens in a nitrogen atmosphere. The variations have again been calculated for 600° C. ambient temperature.

There is a striking similarity in the shapes of the two curves, showing that elastic modulus and expansion coefficient follow one another very closely. It should be noted that although both modulus and expansion measurements were obtained from respective single specimens for each treatment-temperature, the two sets of specimens were cut from two distinct 8 in. $\times$ 8 in. $\times$ 32 in. blocks of carbon. The general variation with heat-treatment temperature is thus quite genuine and cannot be attributed to in-block variations in structure (although no doubt there are minor variations between specimens which would preclude a perfect agreement). This result thus gives support to the void hypothesis.

The changes in expansion are roughly ten times the changes in modulus. This is reasonable if it is assumed that the effect depends mainly on the micropores. The filling-in of these would not affect the mechanical structure very much, but it could lead to large changes in the contribution to the artefact

expansion made by the *c*-axis component of individual crystallites.

Assuming then that void filling is the dominant mechanism, the hysteresis could arise from the inability of crystallites to expand cleanly without overcrowding their neighbours. Some general plastic yielding would then take place before the crystallites reached their full extent, and before the expansion coefficient reached the maximum for the particular temperature in question. On cooling down, the crystallites would shrink back, and this would be a relatively clean process involving rather less plastic yielding. As noted above, dependence of the cooling curve on time has not been detected.

Since the position of the minimum is always close to 200° for materials the pore structure of which is quite different, it is pertinent to ask whether this point does not represent a specific plastic yield temperature rather than some function of the pore structure. The existence of such a yield temperature would be of great interest in interpreting other properties of graphite.

Further investigations are being directed to varying the source material and to exploring thoroughly the low-temperature region.

INFLUENCE OF PTERIDINES ON THE PRODUCTION OF VITAMIN B₁₂ BY TRYPANOSOMID FLAGELLATES*

By HELENE A. NATHAN

Haskins Laboratories, New York

AND

HERMAN BAKER and OSCAR FRANK

Mount Sinai Hospital, New York

IT was noted several years ago that a protozoan parasite of mosquitoes, *Crithidia fasciculata*, required for growth inordinately high levels of a conjugated pteridine; folic acid or still higher levels of folinic acid fulfilled the requirement¹. The lower efficiency of folinic acid emphasized that the role of conjugated pteridines in this organism differs from the microbial pattern in which folic acid functions only in one-carbon metabolism.

The puzzle of this strange pteridine requirement was solved when it was shown² that conjugated pteridines serve two functions in the metabolism of this hemoflagellate: (1) The usual role in one-carbon metabolism; (2) As a precursor of a new class of growth factors, the unconjugated pteridines, previously called the 'Crithidia factor' by Nathan and Cowperthwaite³. We now know that the 2-amino, 4-hydroxy pteridines, which have good *Crithidia* factor activity, are those which are substituted in the 6-position with either—CH₂OH or a longer aliphatic chain with two vicinyl hydroxy groups.

* Substance of a report presented at the third International Symposium on the B-Vitamins at Poznan, Poland, during September 1959.

So far a direct approach to the elucidation of the role of the *Crithidia* factor has been unsuccessful; we have been unable to bypass the growth requirement for the *Crithidia* factor. However, we have recently shown that 2,4,5-triamino-6-hydroxy pyrimidine plus some sugar, such as glucose, can replace *Crithidia* factor⁴. Apparently the protozoan can use the pyrimidine as a pteridine-precursor by converting it to an activated form and closing the incomplete pyrazine ring with glucose.

Now that there are several ways available for satisfying the pteridine requirement of *C. fasciculata* (Table 1, column 1), one way to study the function of the *Crithidia* factor is to measure the variation in key products formed as a function of the compounds used to satisfy the multiple pteridine requirement. Vitamin B₁₂ seemed a key product to measure because it is known that, in certain diseases involving vitamin B₁₂, folic acid sometimes relieves symptoms, whereas in other B₁₂-linked diseases, such as pernicious anaemia, folic acid potentiates neurological involvement. To check the validity of measuring the vitamin B₁₂ formed by *C. fasciculata*, the B₁₂-products formed by

Strigomonas oncopelti, a related protozoan which requires *p*-aminobenzoic acid but no pteridine, were also assayed.

Two-litre batches of *Critidia fasciculata* (Anopheles strain, ATCC 11745) were grown in a defined medium⁶ modified by increased levels of several of the mineral components (a reflexion of the decrease in amounts of contaminating inorganic ions in the organic components of the medium and in the distilled water which is now prepared in a glass still). The organisms were allowed to incubate at about 28° C. until there were about 200 mgm. of cells (dry weight) per litre of culture. The cells were then collected by centrifugation and preserved in a lyophilized state until they were prepared for assay. The culture supernatants were twenty times concentrated and stored at 6° C. until they were prepared for assay.

Strigomonas oncopelti (ATCC 12982) was grown in the medium given in Table 2. Because this trypanosomid does not require haemin as a growth factor, the pH-range for growth may be extended below pH 7.6, where haemin would ordinarily be precipitated from the medium. For these experiments *S. oncopelti* was grown at pH 7.9–8.1, as was *C. fasciculata*, to eliminate the possibility of differences of product due to difference of pH. The same methods were used for incubation, harvesting and storage of both organisms.

250 mgm. of lyophilized cells were homogenized in 25 ml. of pH 4.5 aconitic acid buffer which contained 0.5 per cent metabisulphite⁶. This homogenate was autoclaved at 121° C. for 30 min., diluted to 1.0 mgm. cells/ml. with distilled water, and assayed. Culture supernatants were diluted 1:3 (v/v) with buffer, autoclaved, filtered through paper and assayed.

Vitamin B₁₂ was measured with *Ochromonas malhamensis* and *Euglena gracilis*. We have been accustomed to assume that *O. malhamensis* measures only 'true B₁₂', that is, those forms of vitamin B₁₂ utilizable by humans, and that *E. gracilis* measures 'total B₁₂', that is, those forms to which *O. malhamensis* responds plus other forms (pseudos) which are inactive for humans. Neither of these organisms responds to factor B or nucleotides in place of vitamin B₁₂. These assays could detect 1.0 μ gm./ml. of B₁₂ activity.

As the materials used to satisfy the pteridine requirements of *C. fasciculata* were varied, the amount and kind of B₁₂-activity produced also varied (Table 1). When B₁₂ was detectable there was, in the cells, more total than true B₁₂. On the other hand, for culture supernatants, the results of the assays seemed theoretically impossible: there was more *Ochromonas*-active than *Euglena*-active material (Table 1). Such a disturbing result has been noted before with human sera⁷ and in our unpublished results with sera from patients with liver diseases. There may be a differing ability of the 'true', *Ochromonas*-active and 'pseudo', *Euglena*-active B₁₂ to leak out of the cells, and if so, one might expect varying results for the culture supernatants freed of cells. However, one would not expect the amount of B₁₂ as assayed by *Ochromonas* to exceed that given by *Euglena*. The factor responsible for greater production of *Ochromonas*-active material may either be a special form of vitamin which is only active for *Ochromonas* (and by implication for humans); or it may be some material which releases inhibition of the synthesis of B₁₂ from smaller parts already present; or it may be the long-sought B₁₂-bypass factor.

The role of pteridines in the production of B₁₂-like materials is clearer. For *C. fasciculata*, when there was only enough folic acid present to satisfy the one-carbon function and all the unconjugated pteridines had to be synthesized, presumably from the 2,4,5-triamino, 6-hydroxy pyrimidine also supplied, there was no B₁₂-activity produced (Table 1). For this organism at least, (a) the supply of unconjugated pteridines determines whether B₁₂ will be synthesized and (b) the amount of available conjugated pteridines, or their one-carbon metabolism products (for example, thymidine), influence the kind of B₁₂ produced.

The role of pteridines in B₁₂ synthesis is more strikingly demonstrated in *S. oncopelti* (Table 3). A series was arranged in which *p*-aminobenzoic acid, folic acid, or *p*-aminobenzoic acid plus various pteridines was used to satisfy the *p*-aminobenzoic

* ± 10 mgm. This is the cell crop per litre of medium. The supernatant fluids contained no B₁₂.

acid requirement and to supply possible stimulators for B₁₂ synthesis. Production of B₁₂-activity in *S. oncopelti* cells was unusually high: 300 μgm. *Euglena*-active material/mgm. cells as compared with 28 μgm./mgm. cells for the best *C. fasciculata* yield and 200 μgm. *Ochromonas*-active material/mgm. cells as compared with 5 μgm./mgm. cells for the best *C. fasciculata* yield. Moreover, there was no effect on the balance between *Ochromonas*-active and

Euglena-active material when the pteridines given to *S. oncopelti* were varied; it was uniformly high. In parallel with the results obtained with *C. fasciculata* (Table 1), there was no assayable B₁₂ produced when no exogenous pteridine supply was introduced.

The relatively large quantities of B₁₂ compounds produced by *S. oncopelti* (Table 3) suggest the use of this organism for the concentration and identification of the various forms of the vitamin produced and for the later identification of *C. fasciculata* products. The high yields and the absence of the need for exogenous haem also point to the use of *S. oncopelti* for enzymatic studies of B₁₂ synthesis.

The work was supported partially by a grant from the U.S. Public Health Service. We thank Dr. Helen B. Funk for her many helpful suggestions.

TURNOVERS OF ERYTHROCYTES AND PLASMA PROTEINS IN MAMMALS

By DR. A. C. ALLISON

National Institute for Medical Research, London, N.W.7

MUCH work has been carried out on the survival of erythrocytes and plasma proteins in different animals. In general, a clear pattern has emerged. Plasma proteins disappear from the circulation exponentially, as illustrated by curve A in Fig. 1 (refs. 1, 2). Under favourable conditions of iodination, the rates of disappearance of iodinated proteins or passively transferred antibody globulins (including protein molecules of all ages) are the same as those obtained with proteins after ¹⁴C-amino-acid labelling (in which most labelled molecules are of a similar age)^{3,4}. It follows that removal of plasma proteins from the circulation is a random process which is largely independent of the age of the protein molecules.

This process stands in sharp contrast to the removal of erythrocytes from the circulation. There is substantial evidence that the normal disappearance of erythrocytes from the circulation is linear rather than exponential⁵ (Fig. 1B). Cells labelled by incorporation of isotopic glycine into haem show survival curves of the type illustrated in Fig. 1C. Apart from an initial rapid breakdown, they remain at approximately constant level for a certain period, about 100 days in man, after which they rapidly disappear from the circulation^{6,7}. This suggests that the factor determining their breakdown in or removal from the circulation depends primarily on some property of the aged cell, while external factors are of secondary

importance. The life-span of erythrocytes seems to be controlled by an internal process.

In this article an attempt will be made to show that the turnovers of erythrocytes and plasma proteins, which at first sight seem so dissimilar, may in fact depend on comparable mechanisms. Although reticulocytes contain demonstrable ribonucleic acid⁸, it is generally agreed that mature erythrocytes have no nucleoprotein⁹. Since there is substantial evidence that nucleic acid is involved in protein synthesis, it is scarcely surprising that mature erythrocytes cannot

Fig. 1. A, concentration of labelled plasma albumin in circulation at various times after injection into human subjects; B, concentration of donor erythrocytes at various times after transfusion into normal human recipients; C, concentration of isotopically labelled haem in circulation after a single injection of labelled glycine in human subjects; D, concentration of tricarboxylic acid cycle and haem-synthesizing enzymes in human erythrocytes as a function of their age; E, concentrations of enzymes showing slow decrement rates (for example, lactic dehydrogenase) in human erythrocytes as a function of age; F, concentration of enzymes showing intermediate decrement rates and of adenosine triphosphate in human erythrocytes as a function of age.

synthesize haemoglobin or stromal protein⁷. It is a reasonable deduction that the metabolism of the non-nucleated erythrocyte, upon which the maintenance of a functional cell-membrane and haemoglobin are known to depend, must be carried out by enzymes inherited from the immature, nucleated precursor. The suggestion has therefore been made, and supported by experimental evidence, that there is no synthesis of enzymes in mature erythrocytes and an exponential decay of enzyme activities at different rates during their life-spans⁸.

In human erythrocytes, activities of haem-synthesizing and tricarboxylic acid cycle enzymes decline very rapidly, so that there is no measurable activity in mature cells⁹ (Fig. 1D); this decline parallels the disappearance of mitochondria from maturing cells. Certain other enzymes, for example, lactic dehydrogenase¹⁰ and purine nucleoside phosphorylase¹¹, show only slight decrements in activity in old erythrocytes (Fig. 1E). However, several enzymes show exponential falls in activities in ageing human erythrocytes at rates intermediate between these two extremes (Fig. 1F); such behaviour is shown by glucose-6-phosphate dehydrogenase, phosphoglycer-aldehyde dehydrogenase, DPNH·H⁺ methaemoglobin reductase, catalase and cholinesterase^{8,10,11}. It is noteworthy that the concentration of adenosine triphosphate follows a similar curve in ageing human¹⁰ and rabbit¹² erythrocytes, suggesting that its generation is limited by decline in activity of one or more enzymes at this rate. Since adenosine triphosphate is the immediate source of energy for many important reactions in the erythrocyte, including active uptake of glucose and phosphate and active transport of ions across the cell-membrane⁸, it would not be surprising if fall in concentration of adenosine triphosphate to a critical level results in the disordered metabolism and demise of the cell. It is unlikely that the hexose monophosphate shunt pathway is critical in maintaining the metabolic viability of erythrocytes under normal conditions, since subjects with considerably reduced erythrocyte glucose-6-phosphate dehydrogenase activities show normal life-spans unless exposed to primaquine or other haemolytic agents¹³.

It is of interest that curves 1A and 1F (Fig. 1) are almost superimposable, which suggests that enzymes in erythrocytes decrease in activity at rates comparable with the rates of disappearance of plasma proteins from the circulation. The decrement in enzyme activity in ageing erythrocytes is not due to diffusion out of the cells, since no activity of most of these enzymes is demonstrable in the plasma. It must be due to inactivation within the erythrocyte. Observations on erythrocyte life-spans in different species suggest that the rates of enzyme inactivation in erythrocytes, as well as rates of turnover of plasma proteins, are related to overall metabolism. It has been established and adequately documented¹⁴⁻¹⁶ that small animals have higher specific metabolic rates than large animals under comparable conditions. The metabolic rates of terrestrial mammals can be expressed by the equation $O_2 = 0.0833 B.W.^{-0.27}$, where O_2 is the oxygen consumption in ml. per gm. tissue per min. and $B.W.$ is the body-weight in gm. (equation 1). Several fairly satisfactory methods for determining life-spans of erythrocytes have now been applied to a number of mammalian species. These methods include differential agglutination and haemolysis after injection of cells differing in blood-group specificity from those of recipients, labelling haemoglobin with radioactive iron and

isotopic glycine, and labelling of cells with radioactive diisopropylfluorophosphonate. The use of radioactive chromate gives comparable results within species, but not between species, owing to differences in rates of elution from erythrocytes. Nucleated avian erythrocytes can also be labelled with phosphorus-32 in deoxyribonucleic acid. A review of these methods and their limitations has recently been published by Berlin *et al.*³.

Representative results for different species are summarized in Table 1 (refs. 17-27). In general, there is a reasonable measure of agreement among the results for a single species, although some rather large discrepancies remain to be resolved by further work. From the data in Table 1 it is clear that the erythrocytes of small mammals have shorter life-spans than those of large mammals. When the results are presented graphically (Fig. 2), it appears that there is a straight-line relationship between erythrocyte life-span and the logarithm of body-weight. The regression of life-span (Y) in logarithm of body-weight (X) can be calculated by the least squares method and described by the equation $Y = 23.95X - 1.89$ (equation 2). The sheep erythrocyte has a somewhat longer life-span than expected from this relationship. However, in some experiments with sheep considerable random destruction is evident²⁸, so that the average erythrocyte life-span is probably less than 120 days.

From Fig. 2 and equation (1) it can be concluded that erythrocyte life-span is inversely proportional to the logarithm of metabolic rate. In keeping with such a concept is the report that in human patients with hyperthyroidism erythrocyte life-span is significantly diminished²⁹; the same appears to be true from the data presented for rats made hyperthyroid³⁰. Conversely, in marmots kept in the cold, erythrocyte life-spans are prolonged, the effect being very striking in hibernating animals³¹; similar observations have been made with hamsters³². If there are comparable activities of critical enzymes at the beginning and end of the lives of erythrocytes of different species, it can also be concluded from data summarized in Figs. 1 and 2 that the logarithmic rates of enzyme decrement are proportional to logarithms of metabolic rates.

Birds have high body temperatures and metabolic rates, and it is noteworthy that the life-spans of their nucleated erythrocytes are relatively short²³⁻²⁵ despite some capacity for continued protein synthesis in the circulation. However, the life-span of nucleated erythrocytes of the cold-blooded turtle is reported to

Fig. 2. Regression of erythrocyte life-span against logarithm of body-weight in various mammals (●) and two birds (○)

Table 1. LIFE-SPANS OF ERYTHROCYTES OF VARIOUS SPECIES DETERMINED BY DIFFERENT METHODS

Species	Body-wt. (gm.)	Potential life-span (days)	Method	Ref.
Mouse	23	20-30	Fe-59	17
Mouse	23	41-45	DTP-32	18
Rat	250	50-60	Fe-59	19
Rat	250	(55)	DTP-32	18
Rabbit	2,000	50-75 (70)	N-15 glycine; Fe-59	3
Oat	2,000	68-77 (73)	N-15, Fe-59	20, 21
Dog	13,000	90-135 (95)	N-15, Fe-59	3
Sheep	70,000	120	Fe-59	22
Man	65,000	100-135 (118)	N-15; diff. agglutination	3
Fowl	700	28-35 (31)	DTP-32	
Duck	1,300	39	N-15 glycine; P-32	23
Turtle	120	> 11 months	¹⁴ C-glycine	24
			¹⁴ C-glycine	25
			¹⁴ C-glycine	26

Values in brackets are most probable mean life-spans from available data. Body-weights, unless given, are taken from ref. 27. DTP, radioactive diisopropylthiophosphonate.

Table 2. NUMBER OF TIMES ERYTHROCYTES OF VARIOUS MAMMALS ARE DEOXYGENATED (REHS. IN BRACKETS)

Species	Blood vol. (ml.)	Cardiac output (ml./min.)	Life-span (days)	No. of times deoxygenated
Rat	20 (83)	47 (27)	55	186, 120
Dog	1,000 (34)	1,300 (27)	95	177, 840
Man	5,500 (27)	5,100 (27)	120	160, 344

Table 3. HALF-LIVES OF PLASMA ALBUMIN IN DIFFERENT ANIMALS

Group	Species	Body-wt. (gm.)	α -life (days)	Ref.
A	Cow	185,000	20.7	36
	Man	65,000	15.0	36
	Dog	13,000	8.0	36
	Rabbit	2,000	5.7	36
B	Guinea pig	730	2.8	37
	Rat	250	2.5	36
	Mouse	25	1.9	37
C	Man	65,000	23	1
	Baboon	20,000	16	38
	Rabbit	3,000	8.8	2
	Rat	250	2.6	39

be greater than 11 months²⁶. The rates of incorporation of labelled glycine into circulating turtle erythrocytes were low, suggesting a low rate of replacement of cells and protein. Presumably turtle erythrocytes use up their enzymes so slowly that synthesis in the circulation can nearly maintain the *status quo*.

The relationship between decline in enzyme activity of erythrocytes and metabolic rate may be due to direct effects upon the metabolism of erythrocytes: it is reported, for example, that triiodothyronine increases phosphate turnover by erythrocytes *in vitro*²⁵. But it might also be due in part to variations in cardiac output, which would affect the rates of oxygenation and deoxygenation of erythrocytes. This process, accompanied as it is by ionic fluxes across the cell membrane, is an important metabolic event for the erythrocyte. Assuming random circulation through various organs, the number of times an erythrocyte is oxygenated and deoxygenated is $C.O. \times L.S./B.V.$, where $B.V.$ is the blood volume, $C.O.$ is the cardiac output in the same units of volume per unit time, and $L.S.$ is the average life-span of the cell in the same units of time. This calculation can only be made approximately because of the difficulty of obtaining reliable and representative figures for cardiac outputs. Nevertheless it is of interest that, as shown in Table 2, the number of times an erythrocyte is oxygenated and deoxygenated appears to be of the same order in man, the dog and

the rat, species differing considerably in body-weight. In view of the arguments presented here, it is of interest that the rates of turnover of plasma proteins show a similar dependence on body-weights and hence on metabolic rates of mammals. The results vary somewhat, depending on the technique of labelling, and it has been considered advisable to make independent comparisons of results obtained in two different laboratories where most of the investigations have been undertaken, the Department of Pathology, University of Pittsburgh, and this Institute (groups A, B and D, and C and E, respectively, in Tables 3 and 4). When the logarithms of the half-lives of plasma proteins (Y) are plotted against logarithms of body-weights (X), straight lines are observed (Figs. 3 and 4). Certain considerations deserve special note, however. In the first place, the points for turnover of serum albumin in rodents evidently fall on a different regression line from those of other mammals, suggesting that the metabolism of albumin is different in rodents. This may perhaps be related to the renal glomerular filtration, re-absorption and catabolism of albumin which have been reported in rodents⁴¹. Secondly, it has recently been found that in albuminemic human subjects the half-life of albumin is greatly prolonged⁴², which suggests that the normal mechanism for removal of albumin is poorly developed. Further evidence that plasma protein turnovers are related to metabolism is provided by observations that half-lives of albumin

Fig. 3. Regressions of logarithms of half-lives of plasma albumin in different mammals, as shown in Table 3, against logarithms of body-weights. The values for rodents (curve B) fall on a different regression line from those in other mammals (curves A and C). The equations defining these regressions are: (A) $Y = 0.29X - 0.24$; (B) $Y = 0.12X + 0.12$; (C) $Y = 0.31X - 0.14$.

Fig. 4. Regressions of logarithms of half-lives of γ -globulins, as shown in Table 4, against logarithms of body-weights. The equations defining these regressions are: (D) $Y = 0.26X - 0.03$; (E) $Y = 0.25X + 0.06$.

Table 4. HALF-LIVES OF γ -GLOBULIN IN VARIOUS MAMMALS

Group	Species	Body-wt. (gm.)	Half-life (days)	Ref.
D	Man	65,000	20.3	40
	Dog	18,000	8.0	40
	Monkey	2,500	6.6	40
	Rabbit	2,000	5.7	40
	Guinea pig	730	5.4	40
	Rat	250	5.5	40
	Mouse	25	1.9	37
E	Man	65,000	23	1
	Baboon	20,000	12	38
	Rabbit	3,000	6.6	2
	Guinea pig	730	6.0	1
	Rat	250	5.4	39

and γ -globulin are both shortened by administration of thyroid hormones to experimental animals^{34,40}.

I am indebted to Drs. J. H. Humphrey and J. L. Fahey and Miss M. V. Mussett for advice and to Dr. A. S. McFarlane for permission to quote unpublished findings.

Note added in proof. Since this article was submitted for publication, Drs. Humphrey and Fahey have obtained evidence that the half-life of normal mouse γ -globulin is 4.6 days. Hence the regression proposed in Fig. 4 is probably not valid. The relationship of albumin half-life to body-weight shown in Fig. 3 still stands, which suggests that—as might be expected—the mechanisms of albumin and γ -globulin turnover are different.

TRITANOPIA AND TWO-COLOUR IMAGE SYNTHESIS

By ARTHUR KARP

Psychological Laboratory, University of Cambridge

FURTHER investigations have shown the conclusions of an earlier article¹ to be essentially correct and in harmony with the interpretations of Judd², Walls³ and Wilson and Brocklebank^{3,4}, but in need of clarification and the replacement of generalities with precise information. The topic originates in the fact that, under certain conditions, the image of a scene synthesized with two primary colours that approximate red and blue-green may be as acceptable to an observer anticipating a full gamut of colours as is the image conventionally rendered with three primaries⁵. Furthermore, provided additional conditions are fulfilled, the initial pair of synthesizing primaries may be chosen somewhat arbitrarily, for example, red and white (both incandescent and arc-light) or yellow and green—instead of being limited to red and blue-green⁶⁻⁷.

What is distinctive in such bichromatic systems is not the red and green photographic separations used as a starting point—for these analysing primaries are common to conventional trichromatic systems as well—but the unused blue-violet separation. Thus, as with any visual system which ignores blue-violet light

($\lambda < 490$ m μ approx.), the adjective 'tritanopic'^{8,10,17} applies.

There are three principal constituent phenomena at work, to each of which observers are not all equally sensitive. The first, referred to earlier¹ as "revision of the original primaries", and which will also be called the zero-order hue-change effect, is identified with 'discounting the illuminant' in the 'surface mode of perception', as proposed by Helmholtz and developed by Helson and Judd^{8,18}. That is, on being presented with an unorthodox image, the observer's involuntary cortical processes must, in converting stimulus into perception, make a psychological choice among three possibilities: (1) a two-dimensional pattern of mere coloured patches; (2) the representation of a scene under white illumination with objects of colours the raw stimuli would evoke in isolation; or (3) the representation of a scene under tinted illumination with objects of the colours left after discounting the apparent illuminant. For example, with red and white synthesizing primaries, the choice—if not the trivial case (1)—is between (2) a white-lit scene with red, pink and grey objects, and (3) a scene with red,

white, and blue-green objects under a discounted pink illuminant.

It is convenient to employ, by way of abbreviation, the established terms^{8,9,18} 'aperture' and 'surface' (or object) 'mode of perception' to indicate the choices (2) and (3), respectively. The favouring of the latter choice depends on factors of psychological significance, which may include the depiction of reality, including surface textures, or the presence of some feature seeming to be a diffuse or specular reflector of the apparent illuminant. Analogy may be drawn with another psychological problem, Necker's cube¹⁰, where the choice is between (1) a two-dimensional pattern of twelve line segments, and (2, 3) the representation of a cube in one of two orientations with one of two corners nearest the observer. In the absence of any clues favouring one over the other, the observer's choice, in this particular case, involuntarily oscillates between (2) and (3). It is not surprising that in all such cases of cortical adaptation to a bias a choice may be made without perceptible delay; in tasks such as reading, a printed word or phrase may be recognized in an interval so short it is difficult to appreciate that a dozen or more decisions or bits of information must have been processed in that interval without conscious effort. Due to the difference and distance between stimulus and perception, a mechanical limiting of the stimulus-receiving interval, as with a 1/250-sec. shutter¹², does not necessarily prevent the processing of the stimuli during a subsequent and relatively longer blank interval, following which the perception is delivered full-grown. It is also known that no matter how short the duration of an optical stimulus, the resulting neural activity carries on for at least 1/20 sec.

In synthesized images, the chromaticity of the tinted, or biased, apparent illuminant is represented by the mixture of the synthesizing primaries, whatever their number. If the resultant is to be easily discounted to reveal a wide range of apparent underlying surface colours, it should in general be highly desaturated like the naturally occurring tinted illuminants which do not conceal too much evidence of how the underlying surface colours might appear in daylight. A light pink, for example, is especially satisfactory. Among the saturated apparent illuminants that can be simulated, only yellow (interpretable as white minus blue) is satisfactory, as it resembles the desaturated illuminants in its high intrinsic luminosity and ability to be reflected to some extent by objects of nearly all colours. In order to be discounted, a scene's apparent illuminant may be deduced from highlights or any other features which might be expected to reflect it diffusely or specularly¹, but in the absence of such clues, an average of the luminance and chromaticity integrated within the frame of the image^{8,9} (in effect, a 'virtual neutral-cue') can be readily substituted². Images which lack specular highlights, but are nevertheless surface-mode inducing, result when suitably crossed polarizing filters are located between photoflood lamps and camera¹², or, more simply, when the subject has a mat but textured surface, as does a woollen tapestry or carpet. Appraisal of the quality of images having nothing whatever to serve as a balance-indicating grey scale cannot, however, be intelligently undertaken, lest the seeming richness of some colours be a matter of unbalance in projector intensity rather than a genuinely enhanced effect.

Qualitatively, discounting the deduced apparent illuminant involves its subtraction—or, addition of

its complementary—over the image area. To be more precise, the Judd formulæ⁸ should be used. The construction of Fig. 2. of ref. 1 rapidly gives a qualitatively similar, though less precise, result. In this construction it may perhaps be logical to modify each of the original synthesizing primaries by addition of the complementary of their mixture (W) rather than the complementaries of each other. Thus S' and L' could lie on SW* and LW*, respectively, where W* is located between S* and L*. There is little difference in the final result beyond a foreshortening of S'L'. Another logical correction would be to replace the symbol S with the letter M throughout², because it is the responses of the original scene to the long and middle wave-lengths of visible light that have been recorded, while the short-wave-length response has been ignored.

In its simplest form, the zero-order hue-change effect may be demonstrated with the coloured-shadow display described by Goethe¹³. By combining on a neutral screen the light from two coloured sources, arranged so that an opaque obstacle casts two shadows, the colour of each shadow is seen to be that of one of the light sources combined with the after-image or contrast complementary of the mixture. Thus, for example, orange and yellow-green lights combine to give a very pale yellow field against which desaturated red (orange minus yellow) and desaturated bluish green (yellow-green minus yellow) shadows appear without perceptible delay. The shadow hues (the revised primaries) are a complementary pair; if the original primaries are capable of producing a white field by being nearly complementary and in balance at the outset, no revision takes place. That is, the question of a zero-order hue change does not arise in a two-colour image unless the synthesizing primaries are non-complementary or unbalanced at the outset. Furthermore, it will be seen later that if the synthesizing primaries (whether original or after revision) do not approximate red and blue-green, there will be little or no hue change beyond this point.

In exchanging two new for two old primaries, the zero-order effect has not in general converted a one-degree-of-freedom line of chromaticities into a two-degrees-of-freedom plane of chromaticities; the image is still bichromatic. However, certain hues, like red and blue-green, do change slightly when undergoing desaturation or when varying in luminance relative to a fixed grey scale^{9,11}. For example, increased desaturation yields slight red → orange and blue-green → green shifts at increased luminance as well as slight red → purple and blue-green → blue shifts at decreased luminance. These first-order hue changes, which constitute the second constituent phenomenon and are included in the Judd-Helson formulation^{8,9}, can be observed in the demonstration of Fig. 1(c) of ref. 1. Thus, if M'L' (formerly S'L') roughly parallels the x axis (ref. 1, Fig. 2) the chromaticities perceived may now be chosen from a narrow ellipse of which M'L' is the major axis. Other primary or revised-primary hues, such as yellow-green and violet, however, exhibit little or no such effect¹¹.

The zero- and first-order hue-conversion effects are essentially universal, for they occur with virtually all observers and under a variety of non-critical conditions. Much less universal is a third constituent phenomenon, to be called 'second-order hue shift,' which has been identified as an interchange between colours of equal lightness along a tritanopic confusion locus. (The effect was referred to less precisely in ref. 1 as "overlapping in the subjective distinctions between

colours of equal lightness and adjacent hue.") These particular hue shifts, which alone depart appreciably from a red : blue-green axis, require very critical photographic procedures¹², and are in general very prone to differences among individuals and dependent on subtense and context^{3,4,14}. For example, in a large audience one typically finds a few young women who perceive no important hue shifts away from a red : blue-green axis, although they perceive all the lower-order hue changes readily, and are surrounded by a large body of neighbours who all see a very full gamut of hues without the slightest difficulty. For these reasons, and others given above, it is most convenient to treat the second-order effects separately, and not consider them to be lumped with the grosser lower-order effects, as Judd does².

In colour space, the tritanopic confusion loci are lines of constant lightness (Munsell 'value') and constant 'warmth' or 'coolness'. Typical confusion loci are those joining pale pink with warm yellow, and dark reddish brown with deep purple. The second-order shifts along these loci usually occur in the sense opposite to that of tritanopic reduction¹⁵⁻¹⁷, so the term 'anti-tritanopia' may be adopted. In anti-tritanopia, a slightly greenish yellow hue component can be inserted if luminosity is high but less than that of white, while a blue-violet component can be inserted if luminosity is low but greater than that of black. Such a result might also have been predicted by the Helson effect¹⁸ by noting that the discounted illuminant in any short-wave-deficient arrangement would be expected to be yellowish (although, in the case of red and carbon-arc-white synthesizing primaries (ref. 6, for example) the mixture is not physically yellowish at all), and that Helson specifies that a result of brightness adaptation to such an illuminant is to have relatively light patches take on the (yellowish) hue of the supposed illuminant while relatively dark patches take on the (blue-violet) hue of its complementary. However, it is difficult to identify positively anti-tritanopic shifts with the Helson effect, because the former may be so dependent on the observer, the context, or the subtense. In addition, Helson effect would not allow for the neutral sensations which are retained at all brightness levels.

The blue-violet content of natural and artificial illuminants is extremely variable and is often negligible in the latter. In addition, a part of the foveal region of the retina possesses some short-wave-absorbing pigmentation (the basic purpose of which may perhaps be to reduce chromatic aberration in a high-resolution region). Thus, the perception centres of a normal trichromat would be accustomed to the hue changes, along tritanopic confusion loci, that occur when an image moves on to the affected area of the retina, or when the illuminant varies in short-wave content, and psychological choices would frequently arise. For example, a pale pink patch could be either (1) a pink patch viewed with trichromatic organs in wide-band light or (2) a warm yellow patch viewed with short-wave-deficient organs (if of small subtense) and/or under a short-wave-deficient illuminant (if of arbitrary subtense). The involuntary favouring of choice (2) with little or no perceptible delay could be aided by factors of psychological significance, such as familiarity with the object portrayed or the fact that, in a scene, choice (1) would have led to a less complete¹³ or less aesthetic picture, embodying two instead of three degrees of freedom.

Anti-tritanopia is readily demonstrated in its own right with a bichromatic set of six Munsell chips in

red and blue-green hues only. The 1/2-in. mat chips 7.5 R 5/12 (red), 7.5 R 7/8 (pink), 7.5 R 8/4 (pale pink), 7.5 BG 6/6 (blue-green), 7.5 BG 4/5 (dark blue-green), and 7.5 R 3/5 (dark brown), mounted well apart and in order on a very light grey (N 8/0) background, are recommended. Suitable viewing conditions may be established either at arbitrary subtense with any illuminant lacking wave-lengths shorter than about 490 mμ but otherwise unselective, or at moderately reduced subtense (10'–1°, depending on the individual and the illumination-level) under white light. In either case, the sensations reported are not red, pink, pink, etc., but red, orange, yellow, green, blue and purple, respectively^{3,4}.

In conclusion, the perception of a multiplicity of hues in a well-executed two-colour synthesis of the image of a scene appears to be due to rapid cortical adaptation or orientation to an apparent illuminant seeming to fall on the objects in the scene. Two qualities of the apparent illuminant may be deduced: the quality of being biased away from neutrality, and the quality of being tritanopic, or of rendering only two degrees of freedom. In assessing the second quality, whether or not the first is present, what matters is not the deficiencies in the synthesizing primaries, but the supposed deficiencies in the apparent illuminant simulated by their mixture. The perceived colours are therefore formed from the original stimuli first by discounting the chromatic bias, if any, of the apparent illuminant, and then by discounting the tritanopic reduction due to its apparent omission of short-wave response and the third degree of freedom. Syntheses, the stimuli of which are not converted as described, and are therefore of great significance to some^{2,7}, would be merely patterns which in some way fail to be consistent with, or invite involuntary cortical interpretation as, a representation of surfaces upon which the discountable illuminants fall.

I am indebted, for exchanges of information, to Messrs. Wilson and Brocklebank (who also helped perfect the 'Tritanope's Palette'), W. B. Wintringham (who suggested that tritanopic confusion be considered), D. B. Judd, F. Pollak, and J. M. Adams. The continued interest and encouragement of R. L. Gregory and Prof. W. R. Hawthorne are gratefully acknowledged.

LETTERS TO THE EDITORS

PHYSICS

Effect of Hydrogen-Ion Bombardment on the Oxides of Aluminium and Magnesium

COMMERCIAL high-purity, polycrystalline samples of aluminium oxide and magnesium oxide have been subjected to bombardment by a 300- μ amp. beam of hydrogen ions having an energy distribution with a maximum at 500 eV. At this energy, the maximum penetration into the substances would be of the order of 100 Å., and therefore any changes of property observed would, in the main, be confined to these regions. Changes in electrical resistance have been

Fig. 1. Variation of resistance with bombardment time of: O, magnesia; Δ, alumina

Fig. 2. Recovery of electrical resistance subsequent to bombardment, as a function of $t^{1/2}$ (sec.) for MgO. A, Bombarded for 150 sec.; B, bombarded for 240 sec.; C, bombarded for 300 sec.

recorded as a convenient means of following the effect of the bombardment.

Fig. 1 illustrates the variation of resistance with time of bombardment, and, as can be seen, there is no sign of the observed effect becoming saturated within the time-scale used. Subsequent to bombardment, it was found that the electrical resistance recovered to its original value; this is shown in Fig. 2 for the case of magnesium oxide. Aluminium oxide exhibited a similar behaviour. The full recovery process took place at room temperature, suggesting an activation energy of about 0.1 eV. In addition, the strong dependence of the recovery process on $\sqrt{t}$ (where t is time) is suggestive of a diffusion mechanism. However, further work is required before a full understanding of this effect, which may conceivably have important practical implications, is obtained.

Submillimetre Waves by Harmonic Generation from Cold Cathode Arcs

THE use of the mercury pool arc for microwave harmonic generation has already been described^{1,2}. The purpose of this communication is to report some preliminary results obtained with solid cathodes.

As before, the driving power used was a few watts obtained from a continuous-wave Q-band klystron operating at 35 Gc/s. The arc was mounted in a Q-band wave-guide and was so oriented that the $\frac{1}{2}$ -mm. diameter tungsten-wire anode was parallel to the microwave electric vector. The cathode material in the form of a thin slab was mounted adjustably through the H-plane wall of the wave-guide beneath the wire anode. The arc was struck by applying d.c. to the anode (via a variable resistance) and then moving the cathode until contact was made between it and the pointed end of the anode. The cathode was then withdrawn so that an arc less than 0.1 mm. in length was formed. Harmonic output was collected by means of a smaller wave-guide protruding through an E-plane wall of the Q-band wave-guide close to the arc. No effort was made to match the arc to the output wave-guide.

At high gas pressures (for example, 20 atmospheres argon) disintegration of the cathode material under the action of the cathode spot is much reduced; the cathode spot is clearly emitting at a very high current density, yet the cathode remains 'cold'. It seems that, in principle, any conductor may be used for harmonic generation, but for most materials the cathode spot wanders from beneath the anode wire, thus lengthening the arc and producing a startling drop in harmonic output. Calcium is the most successful cathode tried to date, but even with this material a small movement of the spot can be seen

and this produces a fluctuation in the harmonic power generated. For calcium the d.e. potential across the arc drops from about 15 volts to between 0 and 8 volts when the Q-band drive is switched on. The d.c. current (usually about 0.25 amp.) is adjusted by means of the variable resistance to give maximum harmonic output. This adjustment is very critical.

With a calcium cathode, the ninth harmonic at 315 Gc/s. ($\lambda = 0.95$ mm.) was found, using a Golay infra-red detector for receiver. The highest output so far obtained at this frequency is about 10^{-8} watt, but if the output system can be matched to the arc, the power should approach 1 microwatt. The variation of output power with increasing harmonic number suggests that the ninth harmonic is probably not the highest present, and it is hoped to use a second arc as frequency changer for superheterodyne detection of these higher harmonics.

This communication describes work forming part of the research programme of the National Physical Laboratory, and is published by permission of the Director of the Laboratory.

Dislocations in Non-metallic Layer Structures

A POINT not mentioned by Amelinckx and Delavignette in their communication¹ concerning dislocations revealed in thin flakes of non-metallic layer structures by transmission electron microscopy is the ready observation of grids of crossing dislocations, as distinct from hexagonal net-works, in talc and mica (Fig. 1, cf. Fig. 1 of Amelinckx and Delavignette's communication and Fig. 2).

These grids are generally remarkably stable and may be moved slightly to and fro by varying the

Fig. 1. Grid of crossing dislocations in talc (a hexagonal network is just resolvable in the bottom left-hand corner)

Fig. 2. Crossing of two systems of dislocations in mica

intensity of the electron beam, although if the flake is overheated the dislocations vanish suddenly.

An Electron Microscope Study of Graphite Oxidation

LATTICE or surface imperfections may play an important part as active sites in the oxidation of graphite, and an attempt at observing these and how they behave on oxidation has been made by electron microscopy.

Fig. 1. ($\times c. 10,000$)

Fig. 2. ($\times c. 16,000$)Fig. 3. ($\times c. 16,000$)

Thin films of graphite were prepared by smearing microscope grids over the surface of natural Madagascar flake for examination in an *E.M.6* Metropolitan Vickers electron microscope. These appeared as large areas of flat graphite sheets the basal planes of which were predominantly normal to the electron beam. Dislocations in the basal planes were frequently observed, the estimated density being $10^9/\text{cm}^2$.

Graphite is also particularly prone to the incidence of stacking faults. The basal plane dislocation splits into partials forming a ribbon of stacking fault 700–1000 Å. wide according to the equation:

$$a[10\bar{1}0] \rightarrow a/3[11\bar{2}0] + a/3[2\bar{1}10]$$

From measurements of the radius of curvature of dislocation nodes the stacking fault energy of graphite was estimated at approximately 0.25 erg/cm². Interaction of partials to form networks is shown in Fig. 1.

Due to the fortuitous relative rotation of graphite sheets, moiré fringes are often observed, with dislocations imaged as extra planes. These extra lines are associated with dislocations lying in the basal planes and as these do not pass through the film the analysis of Pashley and Bassett¹ cannot be applied.

Thin films heated in air at 600° C. and examined in the microscope show that attack occurs preferentially at crystal edges and cleavage steps (Fig. 2). Further attack occurs inwards from the initial points (Fig. 3). It would be expected that greater reactivity would occur where dislocations end at crystal edges. Due to the high mobility of these dislocations, considerable movement occurs during heating and cooling and no definite conclusions can be drawn from thin films which have been oxidized outside the microscope. To overcome this, a heating stage has been designed and made for the *E.M.6* microscope and work is now proceeding to oxidize specimens during examination.

I wish to thank the Directors of C. A. Parsons for permission to publish this communication and D. R. Ashworth for supervising the initial work.

Ultra-violet Absorption Spectra of the Molecules H₂O, HDO and D₂O

WE are in complete agreement with Barrett and Mansell¹ concerning the absorption spectrum of water down to 185 mμ, and also in their implied criticism of the work of Golding². Independently of Barrett and Mansell, we had failed to observe with a Unicam SP.500, flushed with nitrogen, the fine-structure described by Golding, and the results were therefore checked on a vacuum grating spectrophotometer³ and extended down to 180 mμ using silica cells of 1 cm. and 1 mm. path-length. Plotted as log *A* against wave-length, the absorbance of water rises nearly linearly down to at least 180 mμ, with no trace of fine-structure. At about 20° C. the absorbance values for 1 cm. path-length were found to be 0.1 at 192 mμ, 1.0 at 186 mμ and 10 at 181 mμ very nearly. More complete and precise results will be published elsewhere.

In the course of private correspondence by one of us with Mr. Golding, a letter from him almost identical with that which follows Barrett and Mansell's communication was received and a full reply was sent. Normal spectrophotometric precautions for work in this region were not observed if the monochromator was not flushed with nitrogen; even in a Beckman DK2 spectrophotometer, the greater part of the light-path lies within the monochromator. Stray light cannot be estimated by using a shutter in the way described; even if it could, it is of interest to compare the percentages of stray light (calculated from the figures given for maximum optical densities with less than 1 per cent error) with corresponding values determined in a more orthodox manner by Stich, Rotzler and Reichstein⁴ for a specially selected DK2 spectrophotometer with complete nitrogen flushing (Table 1).

		Table 1				
		Wave-length	186 m μ	188 m μ	190 m μ	195 m μ
Percentage stray light }	Golding		0.53	0.47	0.18	0.05
	Stieh <i>et al.</i>		4.0	1.3	0.4	0.02

The true stray light will also not in general be appreciably dependent on width of slit; however, if any air remains in the light-path, an effect in the opposite sense to that described by Golding may be observed at the maxima of the Schumann-Runge oxygen absorption bands. Here, as the slits are made narrower, the stray light increases significantly, as might be anticipated; the sharp minima in Golding's spectra occur at the wave-lengths of these oxygen maxima, and together with the abrupt fall at still shorter wave-lengths present an excellent example of the misleading effects of stray light. The statement that Lambert's (rather than Beer's) law is obeyed must be taken with some reserve; it quite certainly would not be obeyed at the wave-lengths of the Schumann-Runge peaks. Sulphuric acid has a remarkably low absorbance down to 185 m μ , so the effect of adding water is not surprising, and of course the same is true for the effect of a solute added to one of a pair of cells containing water—in each case the increase in absorbance results in the appearance of the stray light effects.

Dr. Wilbur C. Kaye of Beckman Instruments, Inc., has informed us that with a properly flushed DK2 spectrophotometer the spectrum of liquid water is in agreement with the results of Barrett and Mansell, and does not show the maximum or fine structure described by Golding.

CRYSTALLOGRAPHY

Crystal Structure of 1-3-7-9 Tetramethyluric Acid and the Molecular Packing in Hydroxymethyl Purine Crystals

THE ability of 1-3-7-9 tetramethyluric acid to solubilize polycyclic aromatic hydrocarbons in water and to form 1:1 and 1:2 crystalline complexes from organic solvents, first pointed out by Weil-Malherbe¹, has recently attracted considerable interest^{2,3}.

Since solubilization and complex formation are closely related, we have investigated the crystal structure of some 1-3-7-9 tetramethyluric acid hydrocarbon complexes by X-ray diffraction hoping to obtain information on the interaction between the purinic and the hydrocarbon molecules. The present investigation of the crystal structure of 1-3-7-9 tetramethyluric acid was undertaken as a first step.

X-ray diffraction photographs were recorded from single crystals of 1-3-7-9 tetramethyluric acid using

a Weissenberg camera and copper $K\alpha$ radiation. [The unit cell dimensions are: $a = 15.59 \text{ \AA}$, $b = 8.87 \text{ \AA}$, $c = 8.46 \text{ \AA}$, $\beta = 118^\circ$, $V = 1033 \text{ \AA}^3$, $Z = 4$, $d_{\text{theor.}} = 1.430$, $d_{\text{exp.}} = 1.422$.

The space group is $P2_1/a$ if a few extremely weak reflexions are ignored.

Both optical⁴ and calculated Fourier transforms^{5,6}, as well as Patterson projections on 010 and 100 were used in the first stage of the structure determination. When a sufficiently large fraction of the observed amplitudes could be assigned correct signs, Fourier projections on 010 and 100 were computed (Figs. 1 and 2).

Atomic co-ordinates were refined through reiterate cycles of structure factor calculations carried out on a 650 IBM electronic computer⁷. The molecules

Fig. 1

Fig. 2

appear to be planar with an average distance of the atoms from the molecular plane:

$$0.0187x + 0.4416y - 0.3655z = 1$$

of $\pm 0.02 \text{ \AA}$.

It is interesting to compare the arrangement of the molecules in the crystal with that of the two parent methylhydroxypurines, theophylline and caffeine⁸. All these structures are monoclinic, with the space-group $P2_1/a$ (ignoring weak forbidden reflexions). However, whereas the crystal structures of theophylline and caffeine are closely related, that of 1-3-7-9 tetramethyluric acid is based on a different type of packing. In caffeine and theophylline, the pairing takes place in the same plane (or almost in the same plane), according to the following scheme:

In the case of 1-3-7-9 tetramethyluric acid the two paired molecules lie in parallel planes 3.5 Å. apart, as shown in Fig. 3.

Fig. 3

From the structure of theophylline alone it might be inferred that hydrogen bonding between $\text{C}=\text{O}$ and $\text{N}-\text{H}$ groups is responsible for the pairing. However, the occurrence of a similar pairing between caffeine molecules, where hydrogen bonding is ruled out by the methylation of the nitrogen, indicates that dipole-dipole interaction may be dominant in both cases. The ring nitrogen atoms forming three σ bonds probably contribute their lone pair electrons (p_z) to the π molecular orbitals. A large fraction of these electron pairs should be localized around the more electronegative oxygen atoms of the $\text{C}=\text{O}$ groups. The mode of pairing of theophylline and caffeine could be

to the strongest N^+-O^- dipole, which arises from the charge-distribution in one molecule being antiparallel to the corresponding dipole in the opposite molecule, as indicated above.

In the case of theophylline, a certain degree of hydrogen bonding might be present in addition to the dipole-dipole interaction, but it would be weakened by misalignment of the oxygen lone pair orbital moments and the $\text{N}-\text{H}$ bond moments to which hydrogen bonding is sensitive⁹. The radical change in the mode of pairing observed in going from caffeine to the 1-3-7-9 tetramethyluric acid structure can

thus be explained by the weakening of the N^+-O^- dipoles resulting from the introduction of one more $\text{N}-\text{CH}_3$ and $\text{C}=\text{O}$ group. It would appear that the strongest N^+-O^- dipoles are now roughly perpendicular to the long axis of the molecules, and that interaction between these dipoles is the main factor responsible for the pairing of the 1-3-7-9 tetramethyluric acid molecules in parallel planes (see Fig. 3). The role of dipole-quadrupole, quadrupole-quadrupole and higher multipole terms is difficult to estimate without calculating the π charge-distribution in the molecule.

Our results show that hydrogen bonding is not necessarily the only specific interaction responsible for the pairing of hydroxymethyl purine molecules, since dipole-dipole interaction may predominate in favourable cases.

A similar suggestion has been recently made by Cannon¹⁰ concerning the interaction between

$\text{N}-\text{H}$ and $\text{C}=\text{O}$ groups of amide bonds.

We wish to thank Dr. F. Ascoli for a gift of 1-3-7-9 tetramethyluric acid crystals. We are indebted to Prof. M. F. Perutz for valuable criticism and for reading the manuscript of this communication. This work was supported by the Consiglio Nazionale delle Ricerche and by a grant from the Rockefeller Foundation.

As part of a programme of work on the investigation of the bond lengths and bond angles in purines¹, the crystal structure of 1,3,7,9-tetramethyluric acid has been determined. In the preceding communication, de Santis, Giglio and Liquori have reported the crystal structure of this substance, but describe a different polymorphic form from the one given here.

Fig. 1. A, $hk0$ Fourier projection with the origin at the centre. Contours are at arbitrary but equal intervals with the zero contour broken. B, 1,3,7,9-tetramethyluric acid showing the positions of the carbon, nitrogen and oxygen atoms in the above projection

I have found that 1,3,7,9-tetramethyluric acid crystallizes from water in two polymorphic forms. Crystals of one form are those described by de Santis *et al.*, and also by Groth when his c axis is halved. The dimensions of the unit cell given by de Santis *et al.* are :

$$a = 15.59 \text{ \AA}, b = 8.87 \text{ \AA}, c = 8.46 \text{ \AA}, \\ \beta = 118^\circ, V = 1033 \text{ \AA}^3$$

The space group is $P2_1/a$ if some fairly weak reflexions of the type $h0l$ with h odd are ignored, but these constitute about 17 per cent of the total number of 'forbidden' reflexions. Crystals of the other form are needles elongated along the c axis, and the unit cell dimensions obtained from rotation and Weissenberg photographs are :

$$a = 10.11 \text{ \AA}, b = 14.89 \text{ \AA}, c = 6.75 \text{ \AA}, \\ \beta = 100.4^\circ, V = 999 \text{ \AA}^3$$

The space group is $P2_1/a$, there being no 'forbidden' reflexions as in the first form, and the unit cell contains four molecules. The smaller volume of this cell indicates that the packing of the molecules is more economical. These crystals appear more suitable for a full structure determination, and hence they were chosen for the present investigation.

The orientation of the molecules and their positions within the unit cell have been determined from the $hk0$ and $0kl$ sharpened Patterson functions in conjunction with structure factor graphs. The coordinates so obtained have been refined by successive Fourier syntheses, and by the method of least squares, the computations being carried out on *Mercury* in the University of London. At the present stage of refinement, the R -factor for the $hk0$ projection is 17 per cent and an $hk0$ Fourier projection is shown in Fig. 1.

Molecules related by a centre of symmetry lie in parallel planes approximately 3.3 Å. apart, and pairs of molecules are related by screw axes. A similar arrangement exists in the other form, the distance between parallel planes being 3.5 Å. A comparison of the two completed structures should prove interesting and should show whether there are any significant differences in the molecular dimensions brought about by the transition from one polymorphic form to the other. The occurrence of weak 'forbidden' reflexions in the other structure suggests that the polymorphic change in 1,3,7,9-tetramethyluric acid represents the rearrangement of an ordered lattice in the structure described here into a disordered one.

Full details of this structure determination and the final results will be published elsewhere.

I should like to thank Prof. E. Boyland of the Chester Beatty Research Institute for the gift of 1,3,7,9-tetramethyluric acid, and the University of London for the award of an I.C.I. Fellowship.

METALLURGY

A Determination of the Melting Point of Element 43 (Technetium)

A SMALL quantity (0.11 gm.) of technetium-99 metal has recently been loaned to us by Oak Ridge Laboratories (U.S. Atomic Energy Commission) and we have taken the opportunity to measure the melting point, as there does not appear to be a value reported in the literature.

Fig. 1. Melting points of metals of the transition series plotted in order of ascending atomic number

The metal, in the form of coarse powder, was contained in a small thoria crucible, and was melted under argon in a tungsten tube resistor furnace of the type described by Haworth and Hume-Rothery¹. The temperature was measured with a Tinsley double-scale disappearing-filament optical pyrometer, by observation through a small hole in the crucible lid. The quantity of metal was not sufficient for the direct observation of melting, but after heating to 2,150° C. the metal had not melted, while after heating to 2,250° C. the powder had melted into a small shiny bead. The melting point may therefore be taken as $2,200 \pm 50^\circ \text{C}$. The molten metal did not attack the thoria, nor does it appear to be volatile at the melting point, only traces of radioactivity being detected on the radiation screens above the crucible of melt.

The melting points of metals of the three main transition series are plotted in Fig. 1 for metals of the Groups IVA to IB of the Periodic Table. It may be seen that technetium resembles manganese inasmuch as its melting point is lower than that of either of the adjacent metals in the series, the melting points of molybdenum and ruthenium, determined in the same apparatus, being $2,610 \pm 20^\circ \text{C}$. and $2,310 \pm 20^\circ \text{C}$. respectively.

Crystallization of Amorphous Niobium Oxide during Anodic Oxidation

STUDIES of the anodic oxidation of metals such as tantalum, niobium, zirconium and titanium have been confined, in general, to temperatures of 25° C. where the thin films formed can be regarded as homogeneous dielectrics and the relationship between $V - t$, $1/C - V$ and $1/C - t$ is rectilinear.

During a study of the anodic oxidation of niobium in a variety of electrolytes (acetic, formic, phos-

Fig. 1. Anodic oxidation of niobium in 1 M acetic acid at a constant current density of 1 m.amp./cm.². Voltage-time relationship at various temperatures showing plateau formation at temperatures greater than 50° C.

Fig. 2. Anodic oxidation of niobium in 1 M acetic acid at a constant current density of 1 m.amp./cm.². Weight gain (ΔW) - time relationship at various temperatures

Fig. 3. Anodic oxidation of niobium in 1 M acetic acid at a constant current density of 1 m.amp./cm.². Reciprocal capacity-time and voltage-reciprocal capacity relationship at 25° C. and 90° C. showing corresponding changes in the slope to those in Fig. 1

phoric, oxalic, chloracetic, boric acids, etc., sodium chloride, strong acids and bases) it has been observed that temperature and current density have a marked influence on the anodizing characteristics. The results are illustrated in Figs. 1, 2 and 3, which show the voltage-time, weight gain-time and voltage-reciprocal capacity relationships respectively for niobium anodized in 1 M acetic acid at a constant current density of 1 m.amp./cm.² at various temperatures.

At 25° C. the $V - t$ curve is rectilinear up to ~190 V, and oxidation proceeds with the formation of interference films, but at higher temperatures the $V - t$ curve is characterized by a plateau, and it is evident that the higher the temperature the lower the voltage at which the plateau occurs. Fig. 2 shows that at 90° C. there is a sudden increase in the $\Delta W - t$ curve which corresponds with the charge required for plateau formation. Similar discontinuities are evident in the $V - 1/C$ and $1/C - t$ curves (Fig. 3).

A similar plateau has been observed with the other electrolytes studied, under appropriate conditions of concentration, temperature and current density.

Fig. 4. Electron micrographs *a*, *b* and *c* correspond to points *A*, *B* and *C* (Fig. 1) and show the initial cracking of the film and subsequent appearance at the surface of the crystalline oxide. Magnification, *a* and *c* $\times 4,250$, *b* $\times 6,500$

Electron diffraction studies of films formed at various voltages at 25° C. and 90° C. have shown that at the lower temperature the oxide surface remains amorphous, but at 90° C., although the oxide gives diffuse haloes of Nb_2O_5 below the plateau, at and above the plateau the structure corresponds to crystalline Nb_2O_5 .

Figs. 4*a*, *b* and *c* show electron micrographs obtained at points *A*, *B* and *C* (Fig. 1) and reveal the initiation of cracks in the surface at the plateau and the subsequent projection of crystals of Nb_2O_5 through the overlying amorphous surface layer. At 25° C., although similar cracks (similar to Fig. 4*a*) appeared at the surface at ~ 190 V., there was no visible evidence of crystallization even after prolonged passage of charge.

From the present work it is evident that initially the oxide surface is continuous and amorphous and that the arrest in the rise in voltage, that is, the plateau, is associated with the formation of discontinuities in the oxide which are caused by crystallization of the amorphous oxide.

Cathcart *et al.*¹ have found that during the high-temperature oxidation of niobium at 350–500° C. the growth law is initially parabolic, but, at a critical thickness which depends on temperature and time, becomes linear owing to cracking of the oxide. From marker experiments they conclude that film growth is due to anion migration through the oxide and that cracking results from the stresses which arise from the formation of the oxide at the metal/metal oxide interface.

Vermilyea² has described the phenomenon of field crystallization where anodically formed amorphous Ta_2O_5 has been shown to crystallize in the presence of a strong electric field and considers that rupture of the amorphous oxide is due to this crystallization which occurs within the amorphous oxide. The similarity of the photomicrographs (Fig. 4) to those obtained by Vermilyea for tantalum indicates that the phenomenon observed in the present work is due to field crystallization and that a similar mechanism is applicable.

Recent electron diffraction studies of thermal oxide films on niobium³ have shown that the oxide is amorphous when protective but is crystalline when non-protective, indicating that film rupture is due to crystallization.

It is apparent from the present work that there are many similarities in the behaviour of niobium during anodic and thermal oxidation, as in both cases film thickening results in discontinuities in the oxide so that oxidation continues linearly. It should be

observed that a protective oxide from the point of view of anodic oxidation is one where film growth proceeds to only a limiting thickness and then practically ceases owing to an alternative electrode process, that is, gas evolution. Fig. 2 shows that film growth of the anodic oxide continues owing to crystallization and consequent film rupture so that the oxide cannot be regarded as truly protective.

It is possible, therefore, that a similar mechanism occurs during the thermal oxidation of niobium and that crystallization of

the amorphous oxide, rather than oxide formation at the metal/metal oxide interface as postulated by Cathcart *et al.*, is the main cause of the stresses which result in discontinuities in the oxide and a linear growth law.

RADIATION CHEMISTRY

Role of Ferrous Hydride in the Oxidation of Ferrous Ion by Hydrogen Atoms

THE oxidation of ferrous ion by atomic hydrogen was recently postulated to proceed by hydride ion formation¹:

Recently the work of Dainton and Peterson² demonstrated the use of nitrous oxide for discrimination between various forms of hydrogen atoms (or their analogues) in γ -irradiated aqueous solutions. This technique may be applied in the establishment of the oxidation mechanism of ferrous ion by hydrogen atoms.

In the pH region up to 2 the radiation-chemical oxidation of ferrous ion solutions containing nitrous oxide by H atoms will proceed by (1) and (2) or alternatively by:

This scheme leads to the following results:

$$(I) \quad G(\text{N}_2) = \frac{G_{\text{H}}}{1 + \frac{k_1 \beta [\text{Fe}^{2+}]}{k_3 [\text{N}_2\text{O}]}}$$

$$(II) \quad G(H_2) = G_{H_2} + \frac{G_H}{1 + \frac{k_2[N_2O]}{k_1\beta[Fe^{2+}]}}$$

where :

$$\beta = \frac{[H^+]}{(k_{-1}/k_2) + [H^+]}$$

and hence :

$$(III) \quad \frac{G(N_2)}{G(H_2) - G_{H_2}} = \frac{k_3[N_2O]}{k_1[Fe^{2+}]} \left(\frac{k_{-1}}{k_2} \right) \frac{1}{[H^+]} + \frac{k_3[N_2O]}{k_1[Fe^{2+}]}$$

The linear plot (Fig. 1) is obtained in good agreement with equation III. From the ratio of the slope to intercept we obtain $(k_{-1}/k_2) = 0.05$ mole litre⁻¹. These results cannot be readily reconciled with any alternative mechanism previously proposed for this reaction :

Mechanism (1.1) is not consistent with the dependence on pH of the G s ratio, while according to the triple collision or the oxidation mechanism involving H_2^+ the intercept in Fig. 1 should be zero.

The oxidation of the ferrous ion by hydrogen atoms externally generated in an electrode-less discharge was recently re-investigated in our laboratory³ over a wide region of H^+ and Fe^{2+} ions concentration. These results yield the value of k_{-1}/k_2 in the region of 0.05–0.02 mole litre⁻¹, in good agreement with the radiation-chemical results.

This ratio of rate constants is consistent with the pH independence of the relative rates of competing reactions of Fe^{2+} and methanol for hydrogen atoms⁴. However, the investigation of the competition between Fe^{2+} and oxygen⁵ requires that k_{-1}/k_2 should be of the order of 0.01.

These results indicate the identity of hydrogen atoms produced by ionizing radiation at low pH and atomic hydrogen externally generated. From Fig. 1 we obtain $k_1/k_3 = 60$ and the application of the value of k_1 , independently obtained^{1,3} leads to $k_2 \sim 10^3$ – 10^4 litre mole⁻¹ sec⁻¹. Thus the interaction of hydrogen atoms as such with nitrous oxide is a relatively slow process, while at pH above 3, efficient

decomposition occurs². This behaviour is analogous to that of hydrogen peroxide in neutral⁶ and acid⁷ solutions. It appears that the hydrogen atom precursor in neutral solutions is the solvated electron, while the 'acid form' is the genuine hydrogen atom. The assumption that the acid form of atomic hydrogen involves only H_2^+ is in disagreement with the slowness of its formation⁸. This species is of importance only in acid solutions where no alternative efficient scavenging of hydrogen atoms occurs, as in the oxidation of I⁻ by hydrogen atoms^{1,8}.

Detection of Photochemical Oxidation of Sulphur Dioxide by Condensation Nuclei Techniques

THE purpose of the tests reported in this communication was to prove that condensation nuclei techniques could be used in a qualitative way in the determination of the predominating reaction. Since quantitative performance depends on controlling several variables, proof that qualitative determinations were possible was needed to justify further work. Since sulphuric acid particles have been found to act readily as condensation nuclei, the manner of their formation from sulphur dioxide in the atmosphere was chosen as the subject of the investigation.

Several investigations have been made of the conversion of sulphur dioxide in the air to form sulphuric acid; for example, those of Blacet¹ and of Gerhard and Johnstone². They indicate that oxidation of the sulphur dioxide by ozone is insignificant compared to the action initiated by the absorption of the radiation by the sulphur dioxide molecule. The molecule then becomes activated. The series consists of the following reactions :

They showed that reaction (5) is of minor importance.

As an example they pointed out that the addition of nitrogen dioxide, which produces ozone catalytically, did not measurably change the rate of production of sulphuric acid, whereas the rate at which sulphuric acid was produced was directly proportional to the amount of sulphur dioxide present.

The tests made here confirm their results. The production of sulphuric acid was detected by a condensation nucleus detector³. It has been found that the condensation nucleus detector is highly sensitive to the presence of sulphuric acid particles in

Fig. 1. Plot of the experimental results (ref. 2) for the radiation-chemical oxidation of 10^{-3} M ferrous sulphate solutions containing 0.01 M nitrous oxide

the air, a sensitivity in some cases better than one part in 10^{12} . However, because several variables affect performance, it was only possible to establish a threshold sensitivity. Some of these variables are the length of time the gas is irradiated by the light, the amount of time that the nucleogenic molecules have to coagulate, and the presence of water vapour to aid in the coagulation process.

Two different arrangements of the apparatus were made to determine what process might predominate. They were designed so that if ozone were the predominant factor in the conversion, the first arrangement would be the more sensitive, whereas if sulphur dioxide irradiation was the predominant factor, the second arrangement would be the more sensitive. In the first arrangement the air was irradiated by the ultra-violet while the sulphur dioxide that was mixed with it was not irradiated. When this procedure was followed no condensation nuclei were produced for several minutes. Those occurring at this time are believed to be due to backward diffusion from the reactor volume of sulphur dioxide into the irradiator, due in part to the pulsating flow of the condensation nuclei detector.

In the second arrangement, the irradiation tube was thoroughly purged with sulphur dioxide so that no air would be irradiated. With the light off, the mixture of sulphur dioxide and air did not produce condensation nuclei. When the irradiator was turned on, the condensation nuclei meter became saturated as soon as the irradiated sulphur dioxide had a chance to pass through the reactor volume to the detector. Due to the extreme sensitivity, it was impossible to introduce such a small amount of irradiated gas that the detector did not become saturated.

Indications are that the life-time of the irradiated sulphur dioxide is quite long. Saturated response was still obtained 30 hr. after irradiation. Evidence that the irradiated sulphur dioxide gas might have been adsorbed by the glass tubing was obtained. It was necessary to purge the tubing for several hours before there was no indication of release of irradiated gas into the condensation nuclei detector. Back diffusion of the irradiated gas into the lecture bottle used as a source of gas necessitated a change to a fresh bottle after a few experiments had been performed.

The irradiator consisted of a special mercury vapour lamp in a quartz tube parallel to another quartz tube through which the air or gas sample could pass. This allows the ozone-producing 1849 Å. radiation to reach the air in the sample tube, as well as passing those lines responsible for absorption in sulphur dioxide.

This experiment shows that it is possible to use the condensation nucleus technique in making analytical studies of reactions in the atmosphere. It has corroborated results made by more elaborate analysis.

I am grateful to Mrs. J. H. Winn for technical assistance.

Rapid Analysis of Erbium by Neutron Activation followed by γ -Ray Spectrometry

It is known that when natural erbium is irradiated with neutrons, erbium-167m (2.5 sec.) is formed¹.

In the present work, a sample (10^{-3} gm.-1 gm., sealed in a polyethylene capsule) is placed in the nuclear reactor JRR-1 for 3 sec. to be irradiated with neutrons at a flux of 4×10^{10} neutrons per cm.²/sec. (when operated at 5-kW. level), cooled for 5 sec., counted for 3 sec., again cooled for 2 sec. and counted for 3 sec. This is done by manual operation. The counting apparatus used is a 256-channel pulse height analyser attached to a 2-in. thick sodium iodide crystal.

In the resultant gamma spectrum the height of photopeak due to 0.208-MeV. gamma-ray of erbium-167m is measured.

The relation between photopeak height and the amount of erbium has been obtained by use of standards which involve erbium in various amounts ranging from 0.01 to 1 mgm.

The coefficient of variation of single analyses has been obtained by use of seven standard samples, each of which includes 156 μ gm. of erbium. The coefficient estimated from seven values is 9.9 per cent, when the average photopeak height is 116 counts per channel and the average area of the peak is 1.9×10^3 counts. Most of the variation seems to originate from error in time measurement, especially for the beginning of irradiation.

Results of analyses are shown in Tables 1 and 2.

Table 1. RESULTS OF ANALYSES FOR SYNTHETIC SAMPLES* MADE OF RARE EARTHS

Sample	Amount of rare earths except erbium (mgm.)	Erbium added (μ gm.)	Erbium found (μ gm.)	Recovery (per cent)
A	0.39	94	94	101
B	1.95	156	164	105
C†	1.95	44	124	80
D	1.95	18.7	28	64
E	1.95	8.7	19.5	104
			9.0	103

* Rare earth elements, except erbium, were mixed in the ratio of natural mixtures (ref. 1).

† The ratio of erbium to other rare earths is equal to that in the natural mixtures.

Table 2. RESULTS OF ANALYSES FOR SAMPLES TO WHICH NO ERBIUM WAS ADDED

Sample	Amount of sample (mgm.)	Erbium found (p.p.m.)
A (Monazite, Malay)	4.57	3.5×10^3
B (Orthite, Korea)	42.4	$< 9 \times 10^1$
C (Soil, dried)	290	$< 3.8 \times 10^1$
D (Vegetable, dried)	1,291	$< 4.0 \times 10^0$
E (Holmium oxide)	14.2	$< 3.0 \times 10^2$

It is hoped to publish a full account of this work in the *Nippon Kagaku Zasshi*.

CHEMISTRY

Formation of Vibrationally Excited Carbon Monosulphide and Sulphur by the Flash Photolysis of Carbon Disulphide

It has recently been shown¹ that a measurable over-population of the excited vibrational levels of a diatomic molecule can be achieved by subjecting it to a high-intensity flash of ultra-violet light in the presence of a high pressure of inert gas, which maintains isothermal conditions. With nitric oxide, electronic excitation:

was followed either by fluorescence or quenching, and by both mechanisms, molecules were produced in the ground electronic states with vibrational energy in excess of the zero point in high quantum yield. The excitation was made to occur without chemical reaction. These phenomena will be of considerable value in the study of energy transfer.

We describe here an extension of the same principle and method to the vibrational excitation of a transient species, produced by photochemical dissociation of a stable molecule. Electronic excitation of the transient by secondary absorption of light ultimately results in the formation of vibrationally excited ground electronic state molecules.

We have found that the carbon monosulphide molecule, produced by flash photolysis of carbon disulphide, is a suitable molecule for a preliminary search for this effect, since it is long lived and has a high absorption coefficient. The main system of carbon monosulphide ($A^1\Pi - X^1\Sigma^+$) (refs. 2, 3, 4) was first observed in absorption by Kondratiev⁵ and later by Porter⁶, who showed that the $C^1\Sigma - B^1\Sigma$ system also occurs in absorption and thereby identified the $B^1\Sigma$ state with the $X^1\Sigma^+$ ground-state. Our re-investigation of the flash photolysis of carbon disulphide, using a medium quartz spectrograph (Hilger E 498), has revealed four important new features.

(1) The carbon monosulphide molecules can be observed in the ground-state with up to at least four vibrational quanta, and the simultaneous cascading of these vibrationally excited molecules down to the level $v'' = 0$ can be followed by kinetic spectroscopy. An example of this is illustrated by Fig. 1, where the charge composition was 0.5 mm. carbon disulphide with 750 mm. of argon, 2,000 joules energy; bands of carbon monosulphide with v'' up to 3 are marked below the diagram. Similar results were obtained using nitrogen as inert gas. The larger the value of v'' , the faster is the rate of decay. It was demonstrated that the vibrational energy was out of thermal equilibrium, by carrying out similar experiments using various pressures of carbon dioxide as inert gas, in which case the absorption spectra of carbon monosulphide molecules with $v'' > 0$ were not observed. If the production of vibrationally excited molecules had been due to an increase of temperature, the effect would have been similar to any inert gas, provided the heat capacity of the system was kept constant. The vibrational energy is probably transferred rapidly to carbon dioxide if it is used as inert gas. Similar proof that the vibration energy is out of equilibrium was obtained by including butene-1

in the carbon disulphide/argon mixtures, which at quite low partial pressures (1 mm.) reduced markedly the concentration of $\text{CS} \cdot X^1\Sigma^+(v > 0)$, and greatly increased their rate of decay. The Q heads of the main system of carbon monosulphide are suitable for quantitative measurement by plate photometry, and the change with time of the vibrational distribution is being investigated. Preliminary measurements show that the rate of production of $\text{CS} \cdot X^1\Sigma^+(v > 0)$ depends roughly on the square of the flash energy, and it may be concluded that the mechanism of vibrational excitation is similar to that referred to above for nitric oxide. The concentration of carbon monosulphide is proportional to the flash energy and the rate of vibrational excitation by secondary absorption of light is proportional to the flash energy, to give an overall square dependence.

Also shown in Fig. 1 are the formation and decay of part of the $v'' = 0$ progression of sulphur. In experiments where even the smallest trace of oxygen was present, the spectrum assigned by Jones⁷ to sulphur monoxide (S_2O_2) in the wave-length region 2700 Å.-3300 Å. was observed very strongly in absorption.

(2) The sulphur vapour spectrum ($B^3\Sigma_u^- \leftarrow X^3\Sigma_g^-$) in the region 2900 Å.-3700 Å., arising from reactions of sulphur atoms produced in the primary step, showed that a fraction of these molecules are also produced with excess vibrational energy; transitions were observed corresponding to v'' up to at least 7. Polymerization of the sulphur occurred rapidly, causing a fast decay of molecules with all v'' values. The fast decay of sulphur relative to carbon monosulphide was reported by Porter⁶.

(3) In addition to the two known systems of carbon monosulphide, some new bands, probably of carbon monosulphide, were observed in absorption, an apparently single-headed band being particularly strong at 2589.04 Å. (air), shaded to the red, which may occur from a transition from the zeroth vibra-

Fig. 1. Formation and decay of vibrationally excited carbon monosulphide by the flash photolysis of carbon disulphide. 0.5 mm. carbon disulphide with 750 mm. argon. 2,000 joules

tional level of the $X^1\Sigma^+$ state. (An alternative explanation is that the new bands are due to an impurity which is formed with, and decays with, carbon monosulphide. However, we were unable to relate them to known spectra which might arise from contamination of carbon disulphide.)

(4) With low pressures of carbon disulphide, < 0.05 mm., the fluorescent spectrum of carbon monosulphide was excited with such intensity by the photolytic flash that the $v' = 0, 1$ and 2 progressions could be recorded on Ilford HP3 plate from one exposure with a slit width of 0.01 mm. The band at 2589.04 Å. referred to under (3) occurred only very weakly in emission. At the higher pressures of carbon disulphide that were required to produce a measurable over-population of the vibrational levels of carbon monosulphide, the fluorescence was completely quenched.

Thus we summarize the mechanism of vibrational excitation of carbon monosulphide as follows:

Influence of Moisture on the Spontaneous Heating of Coal

RESEARCH into the spontaneous heating of coal has been concerned in the past with three well-defined problems. These are measurements of rates of oxidation of coal, measurements of heat produced by oxidation and thirdly the establishment and solution of differential equations describing rises in temperature in oxidizing coal. Recently, measurements of the heat of oxidation of coal in air of controlled humidity have been reported and also heats of desorption and adsorption of water vapour^{1,2}.

In these experiments, sub-bituminous coals (Table 1) always showed a greater rate of loss of heat by evaporation of moisture in a dry air stream than their rate of heat generation by oxidation. This effect is illustrated in Fig. 1, which compares heat produced by oxidation of 4 gm. of coal with loss of heat by drying the same coal in a stream of dry nitrogen of 10 ml./min.

As a result of these experiments it has recently been pointed out that transfer of heat by evaporation of moisture can be of over-riding importance in spontaneous heatings although this factor has previously been neglected³. For example, the linear transfer of

Table 1. TYPICAL ANALYSIS OF SUB-BITUMINOUS COAL, OHAI, SOUTHLAND

As received basis (per cent)	By ash-free and sulphur-free basis (per cent)	
Moisture 17	Carbon 75.0

	Sulphur 0.5 per cent	

Fig. 1

heat by conduction across a temperature gradient in crushed coal is about 3×10^{-4} cal./sec./cm.². If saturated air travels across this gradient and remains saturated but rises in temperature by 1 deg. C., then the increase in heat content of the air is 1×10^{-2} cal./ml. of air and a flow as low as 0.03 ml./sec. across 1 sq. cm. can be responsible for transfer of heat equal to that caused by conduction. Observations of spontaneous heating of coal heaps in New Zealand mines confirm that air travelling through the heaps does remain saturated, though as yet rates of air flow have not been measured.

These results have led to an investigation of the behaviour of sub-bituminous coal the moisture of which has been removed in a vacuum of 0.05 mm. mercury, at 105° C. The coal was crushed to the sizes shown in Table 2 and evacuated in less than 5 min. to minimize oxidation.

Table 2. SIZE ANALYSIS OF COAL USED IN SPONTANEOUS HEATING LABORATORY EXPERIMENTS

+ 1/10 in.	B.S.S.	19 per cent
- 1/10 in. + 60 mesh	B.S.S.	68 per cent
- 60 mesh	B.S.S.	13 per cent
		100 per cent

It has been found that 3 kgm. of coal treated in this way will fire spontaneously in 30 min. from a temperature of 22° C. when oxygen saturated with moisture at this temperature is passed through it at 1 litre/min. The coal is contained in a light aluminium foil cylinder, 12 cm. in diameter and 24 cm. high, with an open top. Air or oxygen enters the coal at a central point 2 cm. from the bottom of the cylinder through a 3-mm. diameter glass tube pushed through the coal from its top surface. Saturated air at 1 litre/min. caused ignition in 12 hr. while dry oxygen ignited the coal in 12 hr. from a temperature of 18° C.

Besides providing a striking demonstration of the importance of humidity in spontaneous heating, this experimental technique allows the spontaneous heating of coals to be studied in the laboratory under conditions of heat transfer resembling those found in practice.

Fractionation of Polystyrene by Gel Filtration

IN a recent paper¹, Porath and Flodin have described a simple and rapid method for the fractionation of water-soluble substances. In this method, which they call gel filtration, aqueous solutions of the substances are applied to the top of a column containing swollen insoluble grains of cross-linked dextrans and are eluted with water; fractions are collected from the bottom of the column in order of decreasing molecular weight. Porath and Flodin ascribe this phenomenon to a form of molecular sieving, the efficiency of which depends on the mesh size of the swollen cross-linked beads. For example, small molecules which penetrate the gel particles will be retarded, while large molecules, which are completely excluded from the gel phase, will migrate without retention in the interstitial fluid.

This communication reports some preliminary experiments in which this technique has been applied to a non-aqueous system, the fractionation of a sample of polystyrene in benzene solution.

Since polystyrene is soluble in non-aqueous solvents such as benzene it is necessary to use substances which swell in these solvents for packing the column. Insoluble cross-linked polystyrene (PSX) beads were used, since it is comparatively easy to prepare such beads with different degrees of swelling (for example, by using various concentrations of the cross-linking agent, divinyl benzene) and thus gels with different mesh sizes. The beads were prepared by suspension polymerization² and the small quantities of soluble polymer, which these beads contain, were removed by packing a column with swollen beads and eluting with benzene until no further polymer could be detected in the eluant.

A sample of polystyrene, having a wide distribution of molecular weights³, was fractionated by a typical chromatographic elution technique using PSX beads of different degrees of swelling (measured by observing the swollen volume of a known weight of beads in the presence of excess benzene). The fractions were recovered by freeze-drying the benzene solutions at the water pump followed by drying to constant weight at 60° C. and were characterized by measuring the specific viscosity (η_{sp}) at one concentration (usually 0.4 gm./100 ml.) in toluene at 30° C.

In Fig. 1 the values of η_{sp}/c are plotted against the cumulative weight together with two reference standards: (a) the horizontal line, which is η_{sp}/c for the whole polymer and represents no fractionation; (b) a plot of the results obtained from a conventional fractionation using the solvent volatilization method³.

It will be seen that whereas PSX beads which swell only 2.2 times give practically no fractionation, with beads having higher degrees of swelling fractionation appears in the lower molecular weight region. In the case of those that swell 51 times, the resolution in this region approaches that of the solvent volatilization method. However, the degree of fractionation in the high molecular weight region is much less pronounced, indicating that even with these beads the degree of cross-linking is not loose enough to allow the larger molecules to penetrate the network.

These preliminary experiments have established, therefore, that high polymeric materials, such as polystyrene, can be fractionated by this technique, and it is thought that, by preparing PSX beads

Fig. 1. Fractionation with cross-linked polystyrene beads. $\times$, PSX 524, degree of swelling 2.2; $\odot$, PSX 509, degree of swelling 13; $\square$, PSX 51, degree of swelling 51.

having a higher degree of swelling and/or by modifying the column technique, the efficiency can be improved to approach that of the conventional fractionation methods. The possibility arises, therefore, of developing a simple method of polymer fractionation in which the fractions can be collected automatically and which is economical in the use of solvents, since most of the benzene can be recovered during the freeze-drying.

A further possible development could be in the separation of very low molecular weight materials (cf. Porath and Flodin, who cite the separation of glucose from dextran fractions of $\bar{M}_n$ 1,000 and 20,000), since although practically no fractionation took place with the PSX beads which swell 2.2 times, a little did, in fact, occur, suggesting that the smallest polystyrene molecules enter the PSX beads.

I wish to thank Miss S. A. Monksfield and Miss H. M. Sankey for assistance with the experimental work and Mr. D. Reichenberg for supplying the PSX beads 509 and 524, and also for his advice on the column procedure. This work is published by permission of the Director of the National Chemical Laboratory.

Nitric Oxide Reduction in Methyl Nitrite Pyrolysis and the Transition from Isothermal Decomposition to Adiabatic Flame

WHEN the lower alkyl nitrite and nitrate esters^{1,2} (RONO and RONO₂) decompose isothermally, they do so by initial fission of the O-N bond yielding an alkoxyl radical RO· and the appropriate oxide of nitrogen. This step commonly controls the rate of isothermal decomposition; the subsequent reactions of the initial products³ determine the stoichiometry. It has generally been assumed that the greater extent of decomposition of nitrates reflects the superior reactivity of nitrogen dioxide, while in the nitrites¹ isothermal decomposition scarcely involves nitric oxide at all:

Views on the inertness of nitric oxide in the methyl nitrite system, first challenged by Carter and Travers³, had to be further revised when the methyl nitrite self-decomposition flame was discovered⁴ in 1955; this flame depends on nitric oxide reduction for its existence.

Two questions arise: (1) How are the adiabatic flame and the isothermal decomposition related?, and (2) How is the transition from decomposition to exothermic flame accomplished?, for if normal decomposition does not proceed beyond nitric oxide and is genuinely thermoneutral, this transition can be induced only by external agencies. The investigation of these questions has thrown new light on the true course of isothermal decomposition.

The adiabatic flame. It has been found that the overall stoichiometry of the decomposition flame lies between the extremes predicted⁴. The products are basically the same as those reported earlier^{5,6} and reaction may be written:

The overall change in enthalpy thus resulting in the flame is $-27.0 \text{ kcal.mole}^{-1}$ and this corresponds to a theoretical adiabatic flame temperature of $1,110^\circ \text{C.}$, which agrees very closely with the experimental^{6,7} value of $1,100^\circ \text{C.}$

Thermal decomposition and flame. Thermal decomposition of the pure vapour at 1 atm. was first studied in a flow system to simulate conditions of the stationary methyl nitrite flame. Even at 250°C. , nitric oxide is reduced and water is formed. Reaction is correspondingly exothermic and thermocouple measurements show a 50 deg. rise in temperature. Thus a path is open by which methyl nitrite pyrolysis may become self-supporting; its potentialities are enhanced by the flexibility of a complex reaction mechanism; as the temperature rises so the stoichiometry alters and more heat is released. Equation 3 adequately represents the decomposition products up to about 500°C. where the self-heating is even more marked.

In the neighbourhood of 590°C. the change in stoichiometry is particularly rapid, and thereafter

differs very little from that of the flame. By 700°C. , a degree of self-heating of nearly 300°C. is achieved; equation 4 summarizes the course of reaction:

Isothermal decomposition. To establish whether the nitric oxide reduction discovered previously is merely a consequence of self-heating, the low-temperature pyrolysis of methyl nitrite has been examined under conditions of constant temperature.

Decompositions were carried out in aged 'Pyrex' reaction vessels using static systems ($178\text{--}310^\circ \text{C.}$) and flow systems ($235\text{--}315^\circ \text{C.}$). Velocity constants and the mean activation energy ($36,400 \text{ cal.mole}^{-1}$) agree with old measurements¹. Nitrous oxide is always formed, the yield never dropping far from 0.13 mole N₂O per mole nitrite decomposed. This figure is independent of temperature (from 235 to 315°), of reactant partial pressure (from 10 to 60 mm. mercury), and of percentage decomposition (from 7.7 to 100). Thus, nitrous oxide is a normal product of isothermal methyl nitrite decomposition:

The mechanism of nitrous oxide formation proposed by Levy⁸ in work on ethyl nitrite seems attractive here. Nitric oxide abstracts hydrogen from free methoxyl and the nitroxyl formed is the source of nitrous oxide. Added nitric oxide (molecular ratio NO:CH₃ONO is 12:1) doubles the nitrous oxide yield without sensibly affecting the rate of reaction:

At low temperatures, nitrogen is never found. It arises only at elevated temperatures, where it may be a product of secondary reactions undergone by nitrous oxide.

Esterification of Fatty Acids with Glycerol

SINCE Berthelot's classical work on the esterification of fatty acids with glycerol, in the last century, considerable work has been done on the topic¹⁻⁴. The presence of 2-monoglyceride in technical products of glycerolysis has been reported recently⁵; this was not noticed by Feuge *et al.*⁴ or by Becker *et al.*⁶ on the ground that 2-monoglyceride is prone to be quickly isomerized to the more stable 1-monoglyceride at the high temperature of the reaction. The present

Table 1. ESTERIFICATION OF FATTY ACIDS BY GLYCEROL

* MG represents monoglyceride.

work on the esterification of lauric, myristic, palmitic, stearic, oleic and linoleic acids with glycerol was undertaken to clarify the question of the formation of 2-monoglyceride in the esterification reaction mixture.

Fatty acid, purified by low-temperature fractionation, was made to react with an equimolar quantity of glycerol at a temperature of $180 \pm 1^\circ \text{C}$, in an inert atmosphere of nitrogen, in the presence of potassium carbonate (0.1 per cent on the weight of fatty acid) as catalyst. Stirring was continued throughout the reaction.

Samples of 1–2 gm. were drawn at intervals of 40, 60, 120, 180 and 225 min. and these were at once treated with 2 drops of 85 per cent phosphoric acid which 'killed' the potash soap catalyst. The mass was dissolved in excess ether and the ethereal extract of the fatty matter washed with cold saturated sodium sulphate solution several times, 5 per cent potassium carbonate solution and finally with water. The washed ethereal solutions were dried overnight with anhydrous sodium sulphate, filtered and evaporated to yield the purified glycerolised product.

1-Monoglyceride and total monoglyceride content of the samples were determined by Pohle, Mehlenbacher and Cook's method⁷, as modified by Handschumaker and Linteris⁸, and Martin's perchloric acid isomerization procedure⁹ respectively; the difference between total- and 1-monoglyceride content represented the 2-monoglyceride content. In a separate set of samples drawn simultaneously from the esterification mixture, the percentage of free fatty acid was determined. The results are given in terms of the particular fatty acid with which the experiment was performed. Expressing the percentage of

free fatty acid in the mixture at a time t as A_t ($A_0 = A_t$, where $t = 0$, A_0 corresponds to 0.5 mole-fraction) and denoting $\frac{A_t}{A_0} \times 100$ by B , the decrease

in the values of A_t and B with time (as also a plot of $\log B$ versus $\log t$) would indicate extent of esterification at any particular time. The observations are noted in Table 1 and Fig. 1.

The results clearly show that 2-monoglyceride constitutes a considerable proportion in the reaction products at various stages. Although it may be true, as suggested by previous workers^{4,5}, that 2-monoglyceride is prone to complete isomerization to 1-monoglyceride at higher temperature, this certainly does not hold good at or below 180°C . It would, therefore, be erroneous to report 1-monoglyceride as total monoglyceride, especially in esterification or glycerolysis reactions (as has been done in the current literature). Ignoring the presence of even a small amount of 2-monoglyceride would lead to wrong computation of the diglyceride content (the hydroxyl value being contributed not only by 1-monoglyceride and diglyceride but also by 2-monoglyceride); and hence also of the triglyceride content in the product obtained from esterification or glycerolysis reaction.

The rate of decrease of free fatty acid in the mixture indicates that the reactivity of fatty acids is greater with low molecular weight and unsaturated fatty acids. This reactivity is apparent, however, as the entire amount of fatty acid is not in a homogeneous phase with glycerol; low molecular weight and unsaturated fatty acids being relatively more miscible in glycerol¹⁰, these react more quickly than the rest. The results obtained are not in full agreement with the observations of Toyama *et al.*¹, but they agree with those of Bhattacharyya and Hilditch².

BIOCHEMISTRY

A Metabolite of 'Carbromal'

'CARBROMAL' (α -bromo diethylacetyl urea) is in widespread use as a sedative and hypnotic. None of its metabolites has, as yet, been fully characterized.

I recently isolated diethylacetyl urea from the intestine contents of a woman who was taking a proprietary drug containing 'Carbromal' 240 mgm. and 'Bromvaletone' 80 mgm. The method of isolation was that using acid ammonium sulphate, described by Nickolls¹; 5 mgm. of the ureide crystallized readily from the neutral, ether-soluble fraction. Purification was by sublimation at 10^{-3} mm. at 100° C. It was at first thought that the product was α -ethyl crotonyl carbamate, which was noted as a product of the reaction of sodium hydroxide on 'Carbromal' by Newberry². Both these compounds and their mixture melted within 5 deg. (200 – 205°); but because of their rapid sublimation these determinations were inadequate. Infra-red spectroscopy clearly differentiated the compound from α -ethyl crotonyl carbamate and from 'Sedormid' (allyl isopropyl, acetylurea). As a result of an examination of the spectra of several compounds in the series a specimen of diethylacetyl urea was prepared by hydrolysis of α -ethylcrotonylcarbamate (Dr. S. Trippett). After sublimation its spectrum in 'Nujol' was identical with that of the compound isolated from the intestines (Fig. 1). It seems probable that this is the compound observed by Turner³.

Fig. 1. The top curve shows the spectra of diethyl acetyl urea; the bottom curve is that of the crystals from the intestines

Thanks are accorded to D. Grime of Imperial Chemical Industries, Harrogate, for the infra-red spectroscopy.

Synthesis of Nicotinic Acid Nucleotides

NICOTINIC acid nucleotide (5'-phospho- β -D-ribofuranosylpyridinium-3-carboxylate) and its adenylyl derivative, adenine-nicotinic acid dinucleotide, have recently been identified as intermediates in the biosynthesis of pyridine nucleotide coenzymes¹. These compounds have been found in fungi^{2,3}, and the mononucleotide has been isolated in small amounts from yeast⁴. Both nucleotides have also been obtained in very low yields by enzymic modification of adenine-nicotinamide dinucleotide (coenzyme I)^{2,3,5}.

It has now been found that nicotinamide nucleotides, which are commercially available, may be conveniently converted into nicotinic acid nucleotides by treatment with nitrous anhydride. Preliminary work showed that nitrous acid or hydrogen chloride in amyl nitrite deaminates adenine nucleotides to hypoxanthine nucleotides, but does not liberate the amide nitrogen from nicotinamide nucleotides.

β -Nicotinamide nucleotide was suspended in dry acetic acid (10 ml. per millimole) and kept at -10° while an equal volume of nitrous anhydride⁶ was condensed in the reaction vessel. The suspension was then kept at 10 – 15° for 1 hr. After removal of volatile material in a stream of dry air, the reaction products were applied to a column of 'Dowex-1-formate' and the nicotinic acid nucleotide was recovered by elution with formic acid¹. The nucleotide was identified by electrophoresis, ion-exchange chromatography and paper chromatography, and by spectrophotometry in the presence and absence of cyanide^{1,3,4}.

When coenzyme I was treated with nitrous anhydride in acetic acid both amide and amine nitrogens were displaced, and hypoxanthine-nicotinic acid dinucleotide was obtained. This dinucleotide was quantitatively hydrolysed to nicotinic acid nucleotide and hypoxanthine nucleotide (inosine-5'-phosphate) by nucleotide pyrophosphatase from potato.

With adenosine triphosphate and magnesium ion at pH 7.6 in the presence of highly purified nicotinamide nucleotide-adenylyl transferase (coenzyme I pyrophosphorylase) from pig liver nuclei the nicotinic acid nucleotide was quantitatively converted into its adenylyl derivative. This derivative was likewise identified by the physical methods described above, and further by its conversion into coenzyme I in the presence of glutamine, adenosine triphosphate, magnesium ion and coenzyme I synthetase from pig liver cytoplasm. The coenzyme I was identified by reduction with ethanol and alcohol dehydrogenase from yeast.

Nicotinic acid nucleotide obtained in this way is a competitive inhibitor of enzymic adenylyl transfer from adenosine triphosphate to β -nicotinamide nucleotide, and is evidently identical with the natural coenzyme precursor.

Proteolysis in Stored Serum and its Possible Significance in Cell Culture

ALMOST all the mammalian cell lines grown in continuous culture require the presence of a small amount of serum protein, usually supplied as whole or dialysed serum. The role of that protein, in an otherwise chemically defined medium¹, is not yet known. It is used to an insignificant degree for the synthesis of cell protein²; and although it is reported to be necessary for the adhesion and flattening of the cells on the glass surface^{3,4}, it is no less essential in suspension cultures. It is here shown that serum protein, presumably because of associated enzymes⁵, undergoes proteolysis on storage at 5° C. or during incubation to yield free amino-acids at a rate which may be significant in certain types of experiments. The amino-acids released are themselves not growth-stimulating since they are already supplied in the medium or are formed from glucose and glutamine. However, other breakdown products of the serum protein, or compounds bound to it and released by its degradation, may be the essential growth factors supplied by serum.

Pooled human serum protein was freed of small molecules by two different procedures. Dialysed serum was prepared by dialysis of serum on a rocking dialyser against running water at 5° C. for 24 hr.; sodium chloride was then added to give a concentration of 0.85 per cent. Gel-filtered serum was prepared by the methods developed by Porath and Flodin⁶. A 3.5 cm. × 40 cm. column (400 ml.) of dextran gel ('Sephadex G-50') was poured and washed with 500 ml. of 0.85 per cent sodium chloride. 100 ml. of serum was allowed to pass into the column and elution was continued with 0.85 per cent sodium chloride. The first 100 ml. of effluent was discarded. The following 120 ml., which contained all the protein, was collected. Small molecules from the serum did not appear in the effluent until another 80 ml. of effluent (300 ml. total) had passed. The column was washed with an additional 500 ml. of salt solution before being re-used.

The dialysed and gel-filtered serum preparations were sterilized by filtration through sintered-glass filters and stored at -20°, 5°, or 37° C. for various times. The free amino-acids were determined on samples which were deproteinized with picric acid⁷

and lyophilized. Portions of the dissolved residue representing 2-4 ml. of serum were analysed on an automatic amino-acid analyser⁸.

The results are presented in Table 1. An analysis of the free amino-acids in a pooled sample of fresh whole serum is included for comparison (column 1). It is apparent from these results that dialysed serum undergoes proteolysis at an appreciable rate even when stored at 5° C. (column 2). After 11 days the amino-acid levels in some cases were as high as those found in fresh whole serum, averaging about 30 per cent. Gel-filtered serum was considerably more stable. After 30 days at 5° C. (column 5), the amino-acid concentrations averaged about a third those observed in dialysed serum after 11 days at the same temperature. The higher stability of the gel-filtered serum was even more evident at 37° C. In an experiment employing one sample of pooled serum (columns 3, 4, 6, and 7), the free amino-acid level in dialysed serum after 5 days was more than half that in whole serum, while in gel-filtered serum it averaged only a tenth. After 28 days the amino-acid levels in dialysed serum had increased on average by nearly 60-fold, but less than 4-fold in gel-filtered serum. At -20° C. only negligible increases were observed in serum prepared by either procedure.

Repeat experiments gave essentially the same results as those reported in Table 1 with some variation between individual lots of serum. In some instances the occurrence of other reactions in addition to proteolysis was indicated by the appearance of amino-acids not present in proteins. The concentrations of citrulline, α -aminobutyric acid, and ornithine which were found in stored or incubated serum are listed in Table 1. The presence of other unidentified ninhydrin-reacting compounds was also indicated by the chromatograms.

It is abundantly clear that dialysed serum stored in the refrigerator cannot be considered to be free of amino-acids. The problem is less serious with gel-filtered serum. The reason for the more rapid breakdown of dialysed serum protein is not clear. It may be related to more efficient removal by the gel-filtration procedure of small molecules necessary as co-factors.

In order to examine the rate of proteolysis under cell culture conditions, dialysed and gel-filtered serums were incorporated at the 10 per cent level

* Dialysed 24 hr. against running water. † Small molecules removed by filtration through 'Sephadex G-50' (ref. 6). ‡ Serum added to a medium (ref. 1), which was complete except for free amino-acids; concentrations calculated for undiluted serum. § Not analysed.

into a medium¹ which was complete except for the essential amino-acids and which was then incubated at 37° C. for 3 days. Free amino-acids appeared at about the same rate as in whole serum. With gel-filtered serum the final amino-acid concentrations were all less than 0.02 mM and averaged about 0.005 mM, calculated for undiluted serum. Dialysed serum released amino-acids at about six times this level.

In experiments in which the essential amino-acids are added to the medium in concentrations greater than about 0.05 mM, the additional amounts released by proteolysis would probably not be significant. At lower levels, however, the free amino-acids contributed by serum protein could have an appreciable effect, particularly in the case of dialysed serum. In one experiment, when cells were grown in a presumably valine-free medium supplemented with 5 per cent dialysed serum and 0.002 mM valine labelled with carbon-14, the specific activity of the valine residues in the cell protein was only 23 per cent that of the precursor amino-acid, the rest deriving from the protein (Eagle, H., and Piez, K. A., unpublished work). Similarly, in the case of the nutritionally non-essential amino-acids, which are synthesized by the cell from glucose and glutamine, the contaminating amino-acids derived from serum proteolysis may introduce a large error in isotope labelling experiments.

Although we have analysed only the free amino-acids formed by proteolysis, it is evident that large numbers of various-sized polypeptides must also be formed, and that some of these may be utilized by cells in culture². Work is in progress in an attempt to evaluate this aspect of serum proteolysis. It is possible that such peptides may be an important and perhaps necessary contribution by serum protein, particularly in the light of the demonstration³ that dialysable substances formed by the action of a dialysed pancreatic extract or crystalline proteolytic enzymes on serum protein can be substituted for the native serum protein in cell growth.

Distribution of Guanylic Acid Residues in Tobacco Mosaic Virus Nucleic Acid

THE mode of arrangement of purine and pyrimidine nucleotides in tobacco mosaic virus nucleic acid was studied using the actions of pancreatic ribonuclease and micrococcal phosphodiesterase. This work showed that in tobacco mosaic virus nucleic acid the purine nucleotides and pyrimidine nucleotides occur in 'clusters' of two or more and also 'singly' alternating with each other. The extension of these studies to nucleic acids of three viral strains (TMV,

HR and M) revealed for the first time significant differences in the arrangement of nucleotides in each of their molecules¹⁻⁵. Additional information on the distribution of guanylic acid residues in tobacco mosaic virus nucleic acid, obtained by the action of an enzyme specific to secondary phosphate esters of guanosine 3'-phosphates, is given in the present communication.

Sato and Egami⁶ recently reported the isolation and properties of a ribonuclease, present in *taka* diastase, which specifically cleaves the secondary phosphate esters of guanosine 3'-phosphates. This important discovery provided a much-desired additional tool for structural studies in ribonucleic acids. This enzyme has been purified in this laboratory using a modified procedure, the details of which will be reported at a later date. My preparations have properties similar to those described by the above investigators. The pH optimum in 0.1 M *tris* buffer was found to be at 7.4. When assayed according to the procedure described earlier⁷ my preparations were found to contain 6×10^4 units of enzyme per mgm. of protein. This enzyme is specific in that it slowly converts guanosine 2':3'-cyclic phosphate to guanosine 3'-phosphate exclusively. It degrades ribonucleic acid giving rise to monoguanlylic acid (guanosine 2':3'-cyclic phosphate, GpI and guanosine 3'-phosphate, Gp) and oligonucleotides terminated by guanylic acid (GpI and Gp). From these results it can be concluded that this enzyme cleaves the ribonucleic acid via transphosphorylation giving rise to guanosine 2':3'-cyclic phosphates and oligonucleotides terminated by them and these are slowly converted to guanosine 3'-phosphates. Its mechanism of cleavage via transphosphorylation is reminiscent of that of leaf ribonuclease⁸ even though the specificities of the two enzymes are different. This enzyme will be referred to here as *taka* ribonuclease-I.

The occurrence of polyguanylic acid segments in tobacco mosaic virus nucleic acid was established using the action of *taka* ribonuclease-I. 2 mgm. of tobacco mosaic virus nucleic acid, prepared according to the heat denaturation procedure⁹, was dissolved in 0.4 ml. of 0.2 M *tris* buffer at pH 7.4 containing 4×10^{-3} M ethylenediamine tetraacetic acid. To this was added 0.1 ml. of *taka* ribonuclease-I (about 1,000 units, a large excess to ensure complete digestion) and a drop of chloroform to prevent microbial growth. The mixture was incubated at 37° for 18 hr. In the complete digest monoguanlylic acid (GpI and Gp) was found to an extent of 26.9 per cent of total guanylic acid residues in tobacco mosaic virus nucleic acid. This was calculated using the base composition data reported earlier¹⁰. Since the enzyme is specific to guanosine 3'-phosphate linkages, the minimum requirement for a monoguanlylic acid to appear in the digest is the occurrence of at least two guanylic acid residues linked together. From this it can be concluded that about 26.9 per cent of total guanylic acid residues in tobacco mosaic virus nucleic acid occur in 'clusters' of two or more, Gp(Gp)_n, where $n = 1$ or more.

The average length of the larger fragments produced by the digestion of tobacco mosaic virus nucleic acid with *taka* ribonuclease-I was determined as follows: 9.2 mgm. tobacco mosaic virus nucleic acid, prepared according to heat denaturation procedure⁹, were dissolved in 1 ml. of 0.04 M *tris* buffer at pH 7.4 containing 10^{-3} M ethylenediamine tetraacetic acid and to this was added 0.1 ml. of *taka* ribonuclease-I (10,000 units) and a drop of chloroform. The mixture

was incubated at 37° for 18 hr. At the end of the reaction time, the digest was transferred to an ice-bath and to this was added with mixing cold 50 per cent trichloroacetic acid. The final concentration of this acid in the mixture was 6 per cent. This was held at 0° for 30 min. and centrifuged at 4° for 15 min. at 2,500 r.p.m. The precipitate was washed with 0.1 ml. cold 6 per cent trichloroacetic acid and this was followed by one washing with 0.5 ml. of cold absolute alcohol. The washed precipitate was dissolved in 2 ml. of 0.02 M borate buffer at pH 8.6. This was then transferred to a dialysis bag and dialysed at 4° C. against 0.02 M borate buffer at pH 8.6 for 8 hr. with continuous stirring. The purine and pyrimidine composition¹¹ of the dialysed preparation was found to be as follows: guanine, 1.00; adenine, 2.17; cytosine, 1.34 and uracil, 1.53. The amount of guanylic acid present in the entire dialysed material was about 29.3 per cent of the total guanylic acid residues in tobacco mosaic virus nucleic acid. This preparation is a heterogeneous mixture of several polynucleotides terminated by guanylic acid. From the purine and pyrimidine composition and the specificity of the enzyme used, it can be suggested that they average about six nucleotides in length, (Xp)_nGp (where X is adenosine, cytidine and uridine), and these are all preceded by a guanylic acid residue in the intact tobacco mosaic virus nucleic acid.

In addition to monoguanlyc acid in the complete digest of tobacco mosaic virus nucleic acid, three dinucleotides, cytidyl-guanlyc acid, uridylyl-guanlyc acid and adenylyl-guanlyc acid and several tri-, tetra-, etc., nucleotides terminated by guanylic acid were isolated. Full details of this investigation will be published elsewhere.

I am indebted to Dr. W. M. Stanley for his encouragement and support of this research.

This investigation was aided by a grant from the United States Public Health Service.

Note added in proof. Guanylic acid residues in a nucleic acid, in addition to occurring in 'clusters' of two or more, (Gp)_nGp, can also occur distributed in two other ways: preceded by pyrimidine nucleotides, cytidylic and uridylic acids, (Pyp)_nGp; and preceded by adenylic acid, (Ap)_nGp. Evidence for this type of distribution in tobacco mosaic virus nucleic acid was obtained by exhaustively digesting the nucleic acid with both pancreatic ribonuclease and taka ribonuclease-1¹². About 46.4 per cent and 28.4 per cent of total guanylic acid residues in tobacco mosaic virus nucleic acid were found to occur as (Pyp)_nGp and (Ap)_nGp respectively.

Biosynthesis of Damascenine in *Nigella damascena* L.

DAMASCENINE is present in the seeds of *Nigella damascena* L. to the extent of about 0.1–0.3 per cent (dry weight). The majority of the alkaloid is present in the testas. The seeds of other *Nigella* species hitherto investigated possess only traces of the base.

In the past few years Tyler¹ as well as Leete, Marion and Spenser² have dealt with the physiology and biosynthesis of damascenine. In order to clarify further the problem of the origin of damascenine in the plant we have studied its ontogenesis and its site of formation; experiments involving the feeding of labelled precursors have also been undertaken.

Damascenine was isolated from the plant material in the usual way and characterized by paper chromatography: circular paper-chromatographic technique was employed using Schleicher and Schüll chromatographic paper 2043 b, which was impregnated with phosphate buffer (pH 8); methanol served as the mobile phase; detection of damascenine (R_F 0.79) was achieved by its characteristic blue fluorescent property under filtered ultra-violet light. While with the help of Dragendorff's reagent (modified after Munier) quantities of more than 30 µgm. of damascenine could be identified on the filter, it required only as low as 1–2 µgm. of the alkaloid to be readily detected under ultra-violet light. Damascenine loses its fluorescing property in acid medium. In order to determine it quantitatively, the base was eluted from the filter with 96 per cent alcohol and with the aid of a reference curve the alcoholic solution was fluorometrically assayed for its damascenine content.

During the course of natural development of the cultivated plants, the damascenine content of different organs of a large number of *Nigella damascena* plants was determined at definite intervals. The seedlings, which were grown in sand, were found to be free from damascenine. This confirms the observations already made by Tyler¹. In the earlier stages of development a very low damascenine content was found in the roots, stems, leaves and flowers; but this gradually increased with the progressive growth of the plants. Beginning with the ripening of the seeds, an enormous increase of damascenine content was noted, and this attained its maximum when the seeds reached maturity. At this stage of development the following values for damascenine content (dry weight) were determined: seeds 0.15 per cent, leaves 0.013 per cent, stems 0.0001 per cent and roots 0.0002 per cent.

In order to locate the site of damascenine synthesis in the plant, excised roots were grown under sterile conditions. Robbins's culture medium was employed, which consisted of 1.5 per cent sucrose, inorganic salts and vitamins, supplemented by the addition of 7 mgm. of arginine per litre (all dissolved in three-times distilled water). The roots were grown in Erlenmeyer flasks, each of which contained 20 ml. of the culture medium. The roots exhibited good growth when they were incubated in dark at 25° C. After an incubation period of 40 days there was on the average 12 mgm. of dried root mass found in each flask. Both the roots and the culture medium were at the end of the incubation period deep yellow in colour. The yellow colouring matter could be readily extracted from the culture medium by shaking it with chloroform (yield: 16 µgm. per

ml. culture solution). Paper-chromatographic investigations of the colouring matter in different solvent systems showed that it consisted of at least two different components, one of which exhibited a yellow, and the other a greenish-yellow, fluorescence in ultra-violet light. Further characterization of these compounds is in progress. Damascenine was present neither in the excised roots nor in the culture medium. Hence it is inferred that the isolated roots are not capable of biosynthesizing damascenine.

Grafting experiments were undertaken to identify the site of the biosynthesis of damascenine in the plant; and to this effect *Nigella damascena* L. was reciprocally grafted on to *Nigella sativa* L. and *Nigella arvensis* L., which are practically free of damascenine. The heteroplastically grafted specimens showed a comparatively smaller longitudinal growth than the ungrafted plants. However, they flowered and developed fruits and ripe seeds in the normal manner. By considering the results derived from a number of analyses carried out on these grafts, it can be established that the roots of *Nigella damascena* do not represent the site of biosynthesis of damascenine. This is in close agreement with the results of the investigations on sterile root cultures described here. It has been found instead that the shoot of *Nigella damascena* is capable of independently synthesizing the alkaloid. It is, however, not known whether the occurrence of damascenine in traces in *Nigella arvensis* as well as in *Nigella sativa* is somehow connected with degradation of damascenine in the plant. Investigations on this problem employing the use of suitably labelled damascenine are under way.

Young leaves of *Nigella damascena*, the stalks of which were dipped in water, were allowed to assimilate in light in an atmosphere of carbon-14 labelled carbon dioxide for a week. 31.2 per cent of the total activity used in the experiment was taken up by the leaves. Damascenine isolated from the dried leaves was purified by paper-chromatographic technique and with the help of radioautography it was found to be radioactive. The isolated damascenine contained 0.256 per cent of the activity taken up by the leaves. In a similar experiment using excised unripe fruits there was no trace of radioactive damascenine to be detected in the fruits chromatographically after having allowed them to stay for two weeks in an atmosphere of labelled carbon dioxide. It may be mentioned here that this is the stage at which the intact plants begin to biosynthesize damascenine at a rapid rate. Hence it can be concluded from these surprising results that the leaves are capable of participating in the biogenesis of damascenine.

As damascenine is a derivative of anthranilic acid, we therefore undertook feeding experiments with labelled anthranilic acid ($-^{14}\text{COOH}$). For this purpose the plants of *Nigella damascena* were aseptically grown in a culture solution containing inorganic salts. With the appearance of fruits on the plants the labelled anthranilic acid was fed (a) by injection into the stem, and (b) to the roots by adding it to the culture solution. After having fed the labelled compound, the test plants were further allowed to grow aseptically for about four weeks, at the termination of which they possessed ripe fruits and seeds; the plants were harvested at this stage and damascenine extracted from different organs was found to be inactive. This means that ^{14}C -carboxyl-labelled anthranilic acid, under these experimental conditions, was not utilized by *Nigella*

damascena plants as a precursor for the biosynthesis of damascenine, or it might have been used up only after the loss of the activity by decarboxylation. Further work in this direction is being continued. The full details of the results obtained will be published elsewhere.

Severe Distortion by 5-Bromouracil of the Sequence Characteristics of a Bacterial Deoxyribonucleic Acid

THE statement is often encountered in the literature that one or another purine or pyrimidine analogue, not found in the cell normally, can, when it is incorporated into a deoxy- or ribo-nucleic acid, partly replace one of the natural nucleic acid constituents. For example, 5-bromouracil is said to replace some of the thymine in deoxyribonucleic acid, or 5-fluorouracil some of the uracil of ribonucleic acid; and this view is even applied to minor constituents occurring in Nature, 5-methylcytosine replacing some of the cytosine, pseudouridine some of the uridine. Such statements are derived, implicitly, from the complementarity principles formulated in this laboratory for deoxyribonucleic acid¹ and ribonucleic acid². But what actually is meant by replacement? If, as is the case, the molar sum of the 6-amino-pyrimidines cytosine and 5-methylcytosine equals the molar concentration of the 6-ketopurine guanine in the deoxyribonucleic acid of rye germ³, does this signify that every cytosine molecule along the polymer chain has an equal chance of being 'replaced' by a methylcytosine molecule? We have recently discussed the evidence for this not being the case⁴.

The procedure for the study of the pyrimidine distribution in deoxyribonucleic acids, which in previous instances permitted differentiation between otherwise indistinguishable nucleic acid preparations from different cellular sources^{4,5}, has again been applied in the present investigation. In a previously studied case, the deoxyribonucleic acid of rye germ, it could be shown that a normal minor constituent, 5-methylcytidylic acid, does not replace the related 6-amino nucleotide cytidylic acid in a random fashion⁵. One of the notable features was, in fact, the much greater tendency of methylcytidylic than of cytidylic acid to be interjacent between purine nucleotides, that is, to occur as what we have termed a solitary unit⁵.

It was, consequently, of interest to study the nucleotide pattern of a deoxyribonucleic acid that

had been forced to admit a minor, abnormal component, 5-bromouracil⁶, ostensibly in the place of thymine^{7,8}. In such systems, no obvious cellular mechanism of regulation, except death itself, can be discerned that would limit the extent of incorporation of the halogenated pyrimidine, whereas the complement of methylcytosine, and presumably also of other natural satellites, appears to be fixed rigidly by the cell^{3,9}.

The purpose of the present work was to ascertain whether, in the deoxyribonucleic acid of an *E. coli* strain requiring thymine, bromouracil really replaces thymine or whether the cell possesses a selection mechanism capable of distinguishing, to some extent, between two 6-ketopyrimidines, the normal thymine and the fraudulent bromouracil; a distinction demonstrated before in the case of the two normal 6-aminopyrimidine constituents of rye germ nucleic acid.

The thymine auxotroph of *E. coli* strain I employed in previous studies⁸ was grown for 18 hr. at 37° on a slightly modified synthetic medium¹⁰ to which 2 µgm./ml. of thymine had been added either alone (prep. 1) or together with 10 µgm./ml. of 5-bromouracil (prep. 2). The deoxyribonucleic acid specimens were isolated by a modification of a procedure employing the treatment of the cells with a buffered phenol-water system¹¹.

Table 1. COMPOSITION OF DEOXYRIBONUCLEIC ACID OF *E. coli* GROWN IN THE ABSENCE AND PRESENCE OF 5-BROMOURACIL

Preparation No.	Growth supplements	Moles constituent per 100 moles total					Molar ratios	
		A	G	C	T	B	$\frac{6-Am}{6-K}$	$\frac{A}{T}$ or $\frac{A}{T+B}$
1	T	24.8	25.0	25.5	24.8	—	1.01	1.00
2	T + B	25.3	24.3	25.1	18.4	9.0	1.01	1.00

A, adenine; G, guanine; C, cytosine; T, thymine; B, 5-bromouracil.

The composition of the nucleic acid preparations is shown in Table 1. It will be seen that, in a formal sense and as regards its total abundance, bromouracil can indeed be said to have occupied more than one-third of the places originally held by thymine.

Table 2. FREQUENCY OF SOLITARY AND COUPLED PYRIMIDINE NUCLEOTIDE UNITS

Preparation No.	Moles per 100 gm. atoms of total nucleic acid phosphorus				
	pTp	pBp	pCp	pOpCp	pCpTp
1	3.82	—	1.78	0.37	1.18
2	3.01	2.96	3.60	0.58	1.38

pTp, pBp and pCp designate the nucleoside 3',5'-diphosphates indicative of solitary units, pOpCp and pCpTp the dinucleoside triphosphates. Compare Table 1 for other explanations and a previous paper (ref. 8) for the description of designations and techniques.

An entirely different aspect emerges, however, when individual positions of the pyrimidine nucleotides within the polymer chains are examined. The findings summarized in Table 2 were obtained by employing stage I of a previously described hydrolysis procedure (30 mgm. deoxyribonucleic acid treated with 1.5 ml. 0.1 M sulphuric acid at 100° for 30 min.)⁴. The separation and estimation of the fragments followed, essentially, the methods using chromatography on exchange resins and filter paper that have been described before³. In this manner,

a fairly complete account can so far be given of the solitary pyrimidine nucleotides, isolated in the form of the corresponding nucleoside 3',5'-diphosphates, and of some of the 'coupled' units, that is, two adjacent pyrimidine nucleotides flanked on both sides by purine nucleotides.

Had an unspecific replacement or displacement of thymine by bromouracil occurred, this would have been reflected in an equal relative utilization of both pyrimidines for common sequences, such as purine—thymine—purine and purine—bromouracil—purine. A glance at Table 2 will show that this is not at all the case. The reorganization of the nucleotide pattern of the deoxyribonucleic acid, brought about by the intrusion of the bromouracil, is so drastic that one receives the impression of dealing with two largely different populations of polymers¹². In the cells grown in the presence of the halopyrimidine, the nucleic acid contains almost twice as many solitary pyrimidine units as does the normal preparation; the frequency of purine—cytosine—purine sequences has doubled and even the relative contribution of thymine to the corresponding units has increased; moreover, nearly one-third of the incorporated bromouracil has been segregated between purines in the form of solitary units. On the other hand, the concentration of the coupled unit purine—cytosine—thymine—purine has been comparatively little disturbed.

A fuller account of this and related work will be submitted later. For the time being, one must conclude that it cannot be stated that thymine has, in a specific sense, been 'replaced' by 5-bromouracil. One gains the impression that, after the selection of equal numbers of 6-aminopurines and 6-ketopyrimidines, on one hand, and of 6-ketopurines and 6-aminopyrimidines on the other, a second mechanism—an exclusion principle, as it were—comes into play, so that certain neighbours are tolerated and others not, or rarely.

We are indebted to Miss J. Mackenzie for assistance and to Dr. S. Zamenhof for the bacterial strain. The work was supported by research grants from the National Institutes of Health, United States Public Health Service, and the American Cancer Society.

¹² The total deoxyribonucleic acid of *E. coli* grown in the presence of 5-bromouracil has been reported to be heterogeneous with respect to the incorporation of this pyrimidine (Bendich, A., Pahl, H. B., and Brown, G. B., in "The Chemical Basis of Heredity", 378 (Johns Hopkins Press, Baltimore, 1957)).

A Method for studying Amino-Acid Activation in Crude Tissue Extracts

THERE IS now considerable evidence that the first step in protein synthesis involves amino-acid activation¹. Using the methods of pyrophosphate exchange into adenosine triphosphate, and of hydroxamate formation, activation of all the common amino-acids, added singly, has been demonstrated in plant², animal³ and bacterial⁴ extracts, although the entire complement of activities is not usually detectable in most preparations⁵. Both these assay methods depend on differences observed in the presence and absence of added amino-acid, and difficulties in interpretation of results arise when applied to crude preparations in which the endogenous level of amino-acids is high. On the other hand, because of the lability of amino-acid-activating enzymes to procedures such as dialysis⁶, any purification procedure to overcome this difficulty carries with it the danger of inactivating part of the enzyme systems being investigated.

In connexion with work on protein synthesis being carried out here, the need was felt for a method of analysing the amino-acid activation pattern in crude cell extracts, and, furthermore, it seemed advantageous that this should be done in the presence of the complex mixture of amino-acids necessary for protein synthesis. The latter consideration seemed especially important in view of the reported competition effects between structurally related amino-acids for the amino-acid-activating enzymes⁴. This

Fig. 1. Progress curve for amino acyl hydroxamate formation by crude 105,000*g* supernatant fraction of a rat liver homogenate. The complete system contained 25 μ moles K_2 adenosine triphosphate, 50 μ moles magnesium chloride, 6,000 μ moles 'low salt' hydroxylamine, 75 μ moles L-amino-acid (mixture containing equimolar concentrations of the 15 amino-acids, alanine, arginine, glycine, histidine, iso-leucine, leucine, lysine, methionine, phenylalanine, proline, serine, threonine, tryptophan, tyrosine and valine), 250 μ moles potassium phosphorylcreatine, 100 μ gm. crystalline creatine phosphoryltransferase, and 1.5 ml. 105,000*g* supernatant. The volume of the reaction mixture was 5.0 ml. and the pH 7.5. Incubations were carried out at 37°.

Fig. 2. Two-dimensional chromatogram of a mixture of 15 synthetic amino acyl hydroxamates

communication describes a method for the quantitative measurement of the total amino acyl hydroxamates formed in the presence of a complex mixture of amino-acids and a further chromatographic procedure for the identification of at least 15 of the individual amino acyl hydroxamates. The procedure is unaffected by the endogenous level of amino-acids in the extracts. The application of the method to crude rat liver preparations as a test system is described here.

Rat liver was homogenized in a Potter-Elvehjem apparatus with 1.5 vol. of ice-cold 0.05 *M* potassium chloride and centrifuged at 105,000*g* for 60 min. Samples of the supernatant fraction were then added to reaction mixtures containing 15 amino-acids, 'low-salt' hydroxylamine, magnesium chloride, adenosine triphosphate and an adenosine triphosphate-generating system in a volume of 5.0 ml. After incubation, the reaction was stopped by the addition of 1.0 ml. of 60 per cent perchloric acid, and diluted with 6.0 ml. of water. The supernatant was collected by centrifugation and the residue washed with water. The combined supernatant and washings were adjusted to pH 7.5 with 3 *N* potassium hydroxide and the precipitate of potassium perchlorate filtered off. The filtrate was evaporated to dryness under reduced pressure at 37° and the residue stored overnight in a desiccator over concentrated sulphuric acid to remove residual hydroxylamine. The residue was extracted with 10 ml. of water and the extract adjusted to pH 5.0 with acetic acid. This solution was then passed through a column of 'Amberlite IRC-50', equilibrated at pH 5.0 with ammonium acetate buffer. After exhaustive washing with water, the column was eluted with 30 ml. of 2 *N* ammonium hydroxide and the eluate evaporated to dryness under reduced pressure at 37°. The residue was dissolved in 5.0 ml. of water and amino acyl hydroxamates determined by the method of

Schweet⁴. Control experiments showed that the column gave consistent 80 per cent recovery values with a mixture of 15 chemically prepared amino acyl hydroxamates. The incomplete recovery is not due to a loss of specific components, since material eluted from the column gave the same loss on recycling. The procedure does not permit the estimation of the hydroxamic acid derivatives of the dicarboxylic amino-acids but does have the advantage of eliminating aspartic and glutamic- ω -hydroxamates, both of which may be formed enzymically^{1,4}.

Fig. 1 shows a progress curve of amino acyl hydroxamate formation by a crude rat liver soluble fraction.

For the identification of the amino acyl hydroxamates present, the dried eluate from 'IRC-50' columns, obtained as above, was extracted with a minimum amount of 90 per cent ethanol. The hydroxamate solution obtained was chromatographed in two dimensions on acid-washed Whatman No. 3 papers, run first in water-saturated 2:4-lutidine, followed by *n*-butanol-acetic acid-water (4:1:1). The spots were detected by spraying with 6 per cent ferric chloride in 0.2 *N* hydrochloric acid. For satisfactory results care must be taken that both ion exchange columns and chromatographic papers are metal-free. The resin was given a preliminary wash with ammonium versenate before use, and the papers were washed in 50 per cent acetic acid and then with water until acid-free⁵. In Fig. 2 the separation of a mixture of 15 synthetic amino acyl hydroxamates is shown. Fig. 3 shows the separation of the mixture of hydroxamates formed by rat liver. The identity of the hydroxamates of glycine, lysine, proline, serine and tyrosine was confirmed by the addition of re-inforcing markers. The spots designated methionine and tryptophan were very faint and could not be identified with certainty. The separation is sus-

ceptible to overloading and this has been shown to be the reason for the distortion of the proline hydroxamate spot. In heavily loaded chromatograms a faint spot corresponding in position to the hydroxamate of histidine has also been observed.

The procedure described here enables identification of at least 15 amino acyl hydroxamates formed simultaneously as a result of amino-acid activation in crude enzyme preparations. With suitable use of labelled amino-acids and carrier marker spots, the sensitivity could doubtlessly be considerably refined. It is also hoped that it may prove possible to apply quantitative methods of estimation to the individual components of the chromatograms.

Full details of this work will be reported later.

Quantitative Isolation of Alkaloids from Plant Materials

THE common methods of isolation of alkaloids in relatively pure forms from plant materials now available involve extraction by solvent partition and/or column chromatography. These methods are very cumbersome, emulsions usually occur, large volumes of solvents are required and the final products are very often impure.

The fact that ammonium reineckate forms insoluble derivatives with alkaloids is well known. The mechanism of the reaction between organic bases and ammonium reineckate has been studied, and the regeneration of the conjugate bases from their reineckates using ion-exchange resins has also been reported¹. This suggests a method for the isolation of plant alkaloids as their insoluble reineckates from which the free alkaloids can later be regenerated by passing an acetone solution of these reineckates through an ion-exchange column. A detailed study of this method was undertaken in order to evaluate it as a means of recovering and determining alkaloids in both opium and *nux vomica*. The procedure yielded crystalline alkaloids even from opium, and the quantitative results obtained indicated a high degree of accuracy and precision. The basic technique can be applied to the isolation of alkaloids from other plant materials provided these alkaloids do not decompose on the ion-exchange column. This simple procedure promises to offer the first method known for the quantitative determination of the absolute amounts of the various alkaloids in opium. The quantitative results obtained for strychnine in *nux vomica* are very satisfactory, and a detailed report of this investigation will be published elsewhere.

Isolation of Opium Alkaloids. About 1 gm. of opium is treated with 50 ml. of 10 per cent hydro-

Fig. 3. Two-dimensional chromatogram of enzymically formed amino acyl hydroxamates. The hydroxamates were formed and isolated as described in the text.

chloric acid for $\frac{1}{2}$ hr. over a water-bath. The solution is filtered through a Whatman No. 1 filter paper and the residue washed with 3 ml. portions of warm dilute hydrochloric acid until the filtrate gave no precipitate with Mayer's reagent. 50 ml. of 2 per cent ammonium reineckate solution is added to the acid solution, cooled to 0°C. and filtered through a sintered-glass crucible with the aid of gentle suction. The precipitate is dissolved in acetone and calcium oxide is added to the acetone solution. A considerable amount of impurities is removed by the calcium oxide in this manner. This solution is filtered through a sintered-glass crucible, and the calcium oxide washed with acetone until the filtrate is colourless. The bright red-coloured acetone solution is then passed through an ion-exchange column of 'De-Acidite FF' which has previously been activated by passing a solution of 5 per cent sodium hydroxide and then washed with water until the eluate has a pH of 7-8. The colourless acetone eluate contains codeine, thebaine, papaverine and narcotine and the morphine is held back in the column. About 20 ml. of water is added to the acetone solution and concentrated to about 10 ml. The solution is made alkaline by the addition of sodium hydroxide and the alkaloids extracted from this solution with chloroform. Crystalline products are obtained on evaporation of the chloroform solution and titration of the residue with 50 per cent ethanol.

The morphine is recovered from the column by first washing the column with water to remove the acetone and then with 10 per cent acetic acid solution. The acetic acid solution is concentrated to about 10 ml. and ammonium hydroxide is added until the solution is alkaline. The ammoniacal solution is extracted with 3:1 chloroform-isobutanol mixture and morphine is obtained upon evaporation of this solvent mixture.

Quantitative Determination of Papaverine in Opium. The chloroform extract containing codeine, thebaine, narcotine and papaverine is not evaporated but is extracted with 3 portions of 20 ml. of *N/5* hydrochloric acid which removes the codeine and thebaine from the organic layer. The chloroform layer is transferred to a separating funnel and 50 ml. of *N/5* hydrochloric acid is added to it. This mixture is shaken thoroughly and 30 ml. of 2 per cent ammonium reineckate solution is then added. The papaverine is determined by the method according to Lee and Farmilo^{2,3}. The results are shown in Table 1. Satisfactory results were also obtained for narcotine. The procedures for the determination of codeine, thebaine and morphine are still under study.

Table 1. - DETERMINATION OF PAPAVERINE IN OPIUM

Amount of opium used (gm.)	Amount of papaverine obtained (mgm.)	Percentage present
1.082	15.1	1.40
1.084	15.4	1.42
1.180	16.0	1.38
1.070 and 10 mgm. papaverine	24.9	1.80

Isolation of Strychnine and Brucine from *Nux Vomica*. 20 ml. of 10 per cent hydrochloric acid is added to 20 ml. of ethanolic extract of *nux vomica* and heated on the water-bath until the ethanol is removed. The acid solution is filtered through a Whatman No. 1 filter paper and the residue is washed with dilute hydrochloric acid until the filtrate gave no precipitate with Mayer's reagent. The strychnine

and brucine are precipitated as their reineckates and the free alkaloids are obtained in crystalline forms using the same procedure as described earlier. Strychnine is determined quantitatively first by treating the alkaloidal mixture with nitric acid and sodium nitrite followed by the extraction of strychnine from an alkaline solution with chloroform. The strychnine is back-extracted from the chloroform solution with acid and afterwards precipitated and determined as its reineckate. The results obtained are shown in Table 2.

Table 2. DETERMINATION OF STRYCHNINE IN *NUX VOMICA*

Volume of <i>Nux Vomica</i> extract used (ml.)	Amount of strychnine obtained (mgm.)	Percentage present
20	74.2	3.71
20	73.0	3.65
20	75.3	3.76
20 and 20 mgm. strychnine	93.7	3.68

I thank the chief chemist, Mr. Chia Chwee Leong, for his interest in this work and for his permission to publish these results.

Action on Some Synthetic Peptides of a Protease from Rabbit Spleen

SOME of the enzymes of bovine spleen have been studied in detail and classified as cathepsin *A*, *B* and *C* according to their specificity for certain synthetic peptides¹. Examination of the action of rabbit spleen extracts on human serum albumin has shown the existence of a proteolytic activity having an optimal pH at 3.0-3.5 (ref. 2). It was shown that this activity was not due to an enzyme analogous with cathepsin *B* or *C* but could have been due to a cathepsin *A* (ref. 3). Recently we have demonstrated that this activity was due to a single protease which we have purified by chromatography on modified cellulose⁴.

This communication deals with the action of the crude rabbit spleen extract and the purified protease on the synthetic peptides specific for the cathepsins *A*, *B* and *C* and carboxypeptidase of bovine spleen. The crude extract and purified protease were prepared from rabbit spleens as described previously⁴. The proteolytic activity of the two enzyme preparations was measured using human serum albumin as substrate⁴. The two preparations were employed in quantities such that their final concentration expressed in arbitrary proteolytic units was 35 U.P. in both cases. The final concentration of the substrates was 0.05 *M* in citrate buffer 0.1 *M*, pH 5.0. Cysteine, at a final concentration of 4 mM, was added to the different substrates with the exception of carbobenzoxy-L-glutamyl-L-tyrosine. The reaction media were incubated at 37°C. for 19 hr. except in the case of the hydrolysis of carbobenzoxy-L-glutamyl-L-tyrosine, by the crude extract, when the incubation time was 5 hr. The moles of carboxylic groups

Table 1. PERCENTAGE HYDROLYSIS OF THE DIFFERENT SYNTHETIC SUBSTRATES

Substrate Enzyme	CGlut	BAA	GPA	CGP
Crude extract, 4.2 mgm./ml	88	60	116	45
Purified protease, 0.60 mgm./ml.	0	0	10	0

CGlut, Carbobenzoxyl-L-glutamyl-L-tyrosine: substrate for cathepsin A; BAA, benzoyl-L-argininamide-hydrochloride: substrate for cathepsin B; GPA, glycyl-L-phenylalaninamide-acetate: substrate for cathepsin C; CGP, carbobenzoxylglycyl-L-phenylalanine: substrate for carboxypeptidase.

liberated during the reaction were measured by the method of Grassmann and Heyde⁶ and the percentage of hydrolysis is given by the relation:

$$\frac{\text{Moles carboxylic groups liberated} \times 100}{\text{Moles substrate employed}}$$

As can be seen in Table 1 the four substrates were hydrolysed by the crude extract, thus demonstrating the existence in rabbit spleen of enzymatic activities analogous with those of cathepsin A, B, C and carboxypeptidase of bovine spleen.

With the purified protease there is no hydrolysis of the substrates specific for cathepsins A, B or carboxypeptidase. There is hydrolysis of the substrate for cathepsin C, but it is minimal and is most probably due to the presence of traces of cathepsin C. These results show that the protease from rabbit spleen is different from cathepsin A, B, C and carboxypeptidase.

The inactivity of the rabbit spleen protease toward the specific substrates of cathepsin A, B and C is an additional property in common between this enzyme and a protease recently isolated from bovine spleen by Press, Porter and Cebra⁸.

Immuno-Electrophoresis of Insulin-binding Antibodies

THE presence of insulin-binding antibodies in the sera of insulin-resistant diabetics has been shown by a large number of investigators¹. It has also been shown by Berson *et al.*² and Kalant *et al.*³ that using paper electrophoresis the binding was mainly in the γ -globulin, while using free-boundary electrophoresis the binding was mainly in the β -globulin. The disadvantage of using paper as a supporting medium is discussed in work now in course of publication⁴. In view of the differences of opinion as to which of the serum proteins is responsible for the binding of insulin it was decided to apply the techniques of immuno-electrophoresis with subsequent autoradiography to the study of diabetic sera.

The insulin was labelled with iodine-131, using iodine monochloride as the carrier by the technique described by McFarlane⁵, and had a specific activity of 3.2 mc. per mgm. insulin. A 1 per cent solution of 'Ionagar' (Oxo, Ltd.) was prepared in a 0.5- μ concentration of barbitone buffer⁶. 15 ml. of this was poured on to glass plates 6 in. $\times$ 2 $\frac{1}{2}$ in., and holes approximately 1.5 mm. diameter were cut at regular intervals along the centre line. Each hole was filled with a serum sample to which had been added about one-tenth of its volume of the tagged insulin solution. The serum samples therefore contained approximately 30 μ gm. of tagged insulin per ml. The volume of sera in each hole was approximately 0.003 ml.

Immuno-electrophoretic controls of bromphenol blue and nitroaniline were used to mark the movement of the albumin and γ -globulin respectively, as suggested by Wunderly⁷. Electrical contact was made through Whatman No. 3 filter paper and a current of 15 m.amp. passed. Small strips of filter paper soaked in the appropriate anti-sera were placed between adjacent holes (Pasteur horse anti-human serum, and anti-S7 γ -globulin-Soothill). The patterns were allowed to develop for 1 week in a moist chamber. The glass plates were then taken out, covered with filter paper to remove the excess protein and salts, and allowed to dry at room temperature. The precipitation pattern was developed in 0.1 per cent nigrosin in 2 per cent acetic acid overnight and then washed in 2 per cent acetic acid to which a little 'Teepol' had been added to remove the excess stain. They were then put on end to dry.

Autoradiography was performed by placing the agar plate in contact with 'Ilflex' double-coated X-ray

Fig. 1. Stained lines on agar plate. Arrows mark positions of strips of antisera. X, Pasteur horse anti-human serum; Y, anti-S7 γ -globulin.

Fig. 2. Autoradiograph. Arrows mark positions of serum samples. Note serum sample 2 is the same serum as sample 1, but one-third of the concentration of active insulin used in all the other samples.

film. Figs. 1 and 2 show the result of this technique. Fig. 1 is a photograph of a section of the stained and dried agar plate showing the results on 6 serum samples; Fig. 2 is the corresponding autoradiograph. In this case with an activity of approximately 0.04 μ c. per sample an exposure of 12 days showed the result illustrated.

It will be seen that in the binding of the insulin two anti-bodies are responsible, one of which corresponds to the S7 γ -globulin and the other to a globulin corresponding in mobility to β -globulin.

It is hoped to report the results more fully shortly and to investigate the binding quantitatively by examination of the density distribution in the appropriate areas of the autoradiograph.

We wish to thank Dr. Soothill for a generous gift of immuno-electrophoretically pure anti-S7 γ -globulin, and Dr. John Bodman for much help with the immuno-electrophoresis.

Regeneration of Visual Pigments from their Low-temperature Photoproducts

UNDER the above title Bridges has recently published an article which describes experiments said to be "in marked disagreement with the picture of the bleaching process" we have proposed¹. We should like to comment briefly.

It has been known for many years that the bleaching of rhodopsin to yellow products—retinene, or indicator yellow—involves a sequence of photochemical and thermal reactions^{2,3}. We have analysed these as follows⁴⁻⁶. Rhodopsin contains 11-*cis* retinene attached as chromophore to a protein, opsin. Light isomerizes the 11-*cis* chromophore to the all-*trans* configuration, yielding a first, highly coloured (red-to-violet) all-*trans* chromoprotein, called lumirhodopsin. All further reactions proceed in the dark, that is, they are thermal reactions. There are at least two of these. First, lumirhodopsin is transformed to another, orange-to-red, all-*trans* chromoprotein, metarhodopsin, by what is probably a configurational rearrangement of the opsin. Metarhodopsin is then hydrolysed to the yellow mixture of all-*trans* retinene and opsin (indicator yellow), and this is probably accompanied by further configurational changes of the opsin.

The synthesis of rhodopsin also can involve both photochemical and thermal reactions. If one mixes 11-*cis* retinene and opsin in the dark, the two join to form rhodopsin by a thermal process⁷. However, if one starts with the products of bleaching in solution—all-*trans* retinene and opsin—the retinene must be

stereoisomerized before it can combine with opsin; and this can be done with light⁸. In this case, therefore, the formation of rhodopsin involves the photochemical stereoisomerization of retinene, followed by the thermal condensation of the appropriate isomer with opsin. Light can also regenerate visual pigments directly from the lumi- or meta-pigments by isomerizing the all-*trans* chromophore to the 11-*cis* configuration^{4-6,9}.

This is not a complete description of the bleaching and synthesis of visual pigments. The presence of further intermediates is implied by other observations, made under different experimental conditions in our own and other laboratories (cf. refs. 10, 11). However, we believe these to be the salient features: (1) photochemical stereoisomerization of the chromophore; (2) configurational re-arrangements of opsin; (3) combination of retinene and opsin by a Schiff base linkage, and its hydrolysis during bleaching. This scheme, first developed on the basis of observations with squid and cattle rhodopsins^{4,5}, has been confirmed with rhodopsins from five other species⁶ (including two of the three used by Bridges), and with the chicken cone pigment, iodopsin⁶.

In view of the number of reactions involved, it is evident that the analysis of the bleaching and regeneration of visual pigments is best performed under conditions such that the partial reactions take place one at a time, or as nearly so as possible. Bridges's experiments do not fulfil this condition, since they are performed in circumstances in which photochemical and thermal processes take place side by side. This is shown by the fact that in his experiments rhodopsin bleaches in the light to "orange products" and indicator yellow. The latter is always a product of thermal reactions, as has been shown repeatedly by lowering the temperature sufficiently during the irradiation (thus allowing only photochemical reactions to take place), and then warming in the dark^{2-4,12}.

It must be clear that this overlapping of reactions makes Bridges's attempt to analyse the bleaching and regeneration of rhodopsin into partial reactions exceedingly difficult. After close examination of his results, we see no present need to revise our interpretation of the mechanism of these reactions.

Hubbard and Kropf's explanation of my results is based on the statement that the experiments were "performed in circumstances in which photochemical and thermal processes take place side by side". The implication here is that irradiation converted the parent visual pigment to an orange photoproduct, and that this photoproduct was unstable and decayed to indicator yellow. This is not so. It was explicitly stated that the orange photoproduct produced by irradiating frog rhodopsin at -5°C . was thermally stable.

Thus irradiation for 1 hr. of frog rhodopsin at -5°C . "generates a mixture of indicator yellow and a stable product with λ_{max} displaced about 20 m μ towards the blue. . . . At this temperature the photoproduct is stable (measurements at 20 m μ intervals from 380 to 620 m μ interlacing with return measurements from 610 to 390 m μ give a check of stability)"¹. The whole spectrum was measured over the course of 1 hr., that is, the same period of time as for the bleaching operation. In the experiments carried out with conger eel and rhesus rhodopsins, the return measurements were actually slightly higher than the outward ones; far from decaying thermally to indicator yellow, the orange photoproduct was being regenerated from this substance.

It was shown experimentally that the rhesus photoproduct was photosensitive, yielding indicator yellow or retinene by a photochemical reaction. As was stated, the probable explanation for the presence of indicator yellow together with thermally stable orange photoproducts in the frog and conger eel experiments is that it was the product of photochemically bleaching these substances.

The use of light of long wave-length in the experiments reported (dominant wave-lengths of 550 and 580 m μ obtained from a Hilger-Barfit monochromator) makes it unlikely that regeneration from photoisomerized indicator yellow was involved in the thermal regeneration of rhodopsin. Even in the acid solutions used, indicator yellow has λ_{max} no higher than 440 m μ , and later experiments at pH 9.0, where indicator yellow has λ_{max} at 380 m μ , have yielded identical results.

BIOPHYSICS

Plasticity of Wool

The quality of a wool is not determined solely by the dimensional characteristics of the fibres, such as fineness, length and crimp. Differences in the nature of the substance govern the selection of wools for particular purposes, and it has been shown that these differences can be measured by determining the plasticity of the fibres¹. The measurements are made by observing the rate of creep of the fibres in distilled water at 22.2°C ., usually under a constant load of 6 kgm./mm.². When $\log (E - E_t)$ is graphed against t , where E_t is the percentage extension at time t (min.), and E is an arbitrarily chosen limiting extension, a linear relationship is obtained in the later stages of extension; the slope (k) of this line gives a simple measure of plasticity.

Because plasticity measurements are tedious, there have been several attempts to devise more rapid methods of characterizing the substance of different wools, and le Roux² has suggested that there is a simple direct relationship between the plasticity of a wool and its urea-bisulphite solubility³. This possibility had been examined in these laboratories before the publication of le Roux's note, and as the two sets of results were found to be contradictory, further experiments have since been carried out. Most of the wools in the new group were from South Africa, because le Roux's work was confined to such wools. Plasticity measurements were made under the conditions defined above, and the rigidly defined conditions of Dusenbury were adopted for determinations of urea-bisulphite solubility⁴. Both sets of results are given in Table 1.

Table 1

Wool	Plasticity (k)	Urea-bisulphite solubility (%)
64s Port Elizabeth Graasveld	91.4	55.0
80s Port Elizabeth Graasveld	86.2	41.2
66s East London	77.6	68.0
70s Cape Town	70.8	48.0
64s Cape Town	75.8	57.6
Cape Town	95.8	53.4
Queensland	42.6	47.8
70s Durban	92.6	60.8
64s Durban	73.1	56.2
60s Durban	112.8	57.9

These results, like the earlier ones, indicate that there is no simple relationship between the plasticity of wool and its urea-bisulphite solubility.

Orientation of Cockchafer

A PAPER by Dr. F. Schneider published in 1957¹ suggested that cockchafer can orientate themselves in the magnetic field of the Earth. I have therefore carried out some experiments to detect the possible existence of permanent magnetic material in the body of cockchafer.

Two methods were used. First, I suspended parts of dead cockchafer at the end of a thin glass wire (length 1 metre, diameter 25 μ) and in a magnetic field up to 20 gauss. It was found that no magnet could be present of such strength that in a field of 0.2 gauss it would experience a torque of more than 2×10^{-6} dyne cm. In the second method I used very sensitive magnetometers of the Royal Netherlands Meteorological Institute, De Bilt, which enabled me to make measurements on living animals. These measurements showed that in a field of 0.2 gauss the torque exerted on the supposed magnet must be smaller than 2×10^{-7} dyne cm.

If the supposed magnet were 0.01 cm. long, the mechanical force exerted by one pole of the magnet would have to be 2×10^{-5} dyne to produce a torque

of 2×10^{-7} dyne cm. If we suppose that the sense cells are stimulated by the pulling of a hair, then it is reasonable (assuming that elongation of a hair of about 1.4×10^{-10} cm. is detectable and Brownian motion limits the natural sensitivity of sense cells) to accept the threshold for the perceptible force as about 0.1 dyne (according to Hl. de Vries). Therefore I conclude that, if the cockchafer has permanent magnetic material at all, it cannot exert a mechanical force in the Earth's magnetic field greater than 2×10^{-5} dyne, which is much too small to be perceived by the sense organs of the cockchafer.

PHYSIOLOGY

Hypoglycæmic Response to Leucine in a Leucine-sensitive Man

It has been reported previously^{1,2} that certain individuals show a profound lowering of the blood glucose-level following ingestion of leucine or isovaleric acid and that this is a familial trait.

We have studied the mechanism of this hypoglycæmic response in a fasting leucine-sensitive male aged 29 years (case 3¹) using methods previously described to follow peripheral glucose metabolism in the forearm^{3,4} and plasma insulin activity⁵. Following successive infusions into the brachial artery at rates of 7 mgm./min. for 20 min. of L-leucine and commercial isovaleric acid neutralized in saline, 10.5 gm. L-leucine was taken by mouth.

Fig. 1. Above, arterial blood glucose concentration ●—●, and glucose threshold ○—○; middle, glucose uptake by the tissues of the fore-arm (mgm. glucose removed from the arterial blood per 100 ml. tissue per min.); below, arterial plasma insulin activity (μgm. glucose taken up per 10 mgm. dry weight of rat hemi-diaphragm)

Fig. 1 shows the arterial blood glucose-level and plasma insulin activity, the glucose uptake and calculated glucose threshold of the fore-arm tissues. Neither leucine nor isovaleric acid, when continuously infused, affected the glucose uptake or glucose threshold of the fore-arm tissues. The oral dose of leucine, however, lowered the blood glucose-level and the tissue glucose threshold. The arterial plasma insulin activity increased significantly ($P < 0.05$) from 139 ± 20 to 212 ± 19 μgm. glucose/10 mgm. dry weight rat hemi-diaphragm/90 min. incubation, but this increase was only transient, results in accord with those published recently by Yalow and Berson⁵.

The subsequent fall in the glucose threshold of the fore-arm tissues resembled that observed in normal individuals after injections of insulin⁴. It may be noted that the systemic fall of blood sugar was not accompanied by an increase of glucose uptake by the fore-arm tissues; this has also been observed in other subjects after intravenous insulin.

We conclude that: (1) it is unlikely that the peripheral tissues take up more glucose as a direct response to circulating leucine or isovaleric acid; (2) the hypoglycæmic effect of leucine in sensitive subjects is due to a transient rise in the plasma insulin activity.

Effect of Strophanthin G on Oxidative Metabolism in Cardiac Muscle

PREVIOUS results published from this laboratory indicate that the increased mechanical efficiency (ratio of work output to energy input) apparent after the administration of non-toxic doses of cardiac glycosides to isolated spontaneously beating hearts is invariably associated with raised levels of oxidative metabolism^{1,2}. Hajdu and Leonard³ recently directed attention to the possibility that such an increased rate of oxygen consumption could be due to the increased mechanical work output associated with the positive inotropic response rather than to the fundamental metabolic action of the glycosides themselves.

An attempt has been made to investigate this possibility by comparing the effect of strophanthin G ('Ouabain' (Arnaud): Laboratoire Nativelle product) on the rate of oxygen uptake in actively beating hearts with that on hearts in systolic and diastolic arrest.

Experiments were carried out at 25.0° C. on hearts isolated from unselected summer toads (*Bufo*

Fig. 1. Effect of strophanthin *G* (10 μ gm./ml.) on the rate of oxygen consumption of actively beating hearts (mean 12 exp.) and hearts arrested in diastole (mean 6 exp.) and systole (mean 6 exp.). The drug was added at the arrow

marinus), using the perfusion apparatus and fluid previously described⁴. In six preparations isolated hearts were initially arrested in diastole by the addition of neutralized potassium chloride solution (minimal concentration). The rate of oxygen uptake was recorded at 15-min. intervals both during an initial control period of 1 hr. and throughout the 2 hr. following the addition of strophanthin *G* (final concentration 10 μ gm./ml.). In a similar series hearts were arrested in systole by the administration of calcium chloride (neutralized), and the effect of strophanthin *G* on the oxygen consumption recorded as above. These results were compared with those previously recorded following the administration of strophanthin *G* at this same concentration to a series of actively beating hearts. The necessary control experiments were also carried out.

The results recorded are summarized in Fig. 1, from which it is evident that strophanthin *G*, at a concentration sufficient to produce a positive inotropic response⁴, stimulated oxidative metabolism in actively beating hearts but failed to do so in those arrested either in diastole or systole. Similar observations were made in other experiments in which lanatoside *O* ('Cedilanide', Sandoz Ltd. product) was used (20 μ gm./ml. final concentration). The rate of oxygen utilization in both the diastolic and systolic arrested control experiments gradually fell throughout the 3-hr. experimental period, while that of the control series of actively beating hearts remained relatively constant.

During the initial hour's perfusion, hearts arrested by potassium averaged an oxygen consumption of 1.59 ml./min./100 gm. wet weight (mean 12 exp.) compared with that of 4.233 ml./min./100 gm. wet weight (mean 10 exp.) recorded in the calcium arrested series.

These results demonstrate that, whereas the glycosides stimulate oxidative metabolism in actively beating hearts, they fail to do so in hearts which have been arrested. It may be argued that the increased rate of oxygen utilization recorded in the active series resulted from an effect of the glycosides on a specific stage during contraction or relaxation. Alternatively, as suggested by Hajdu and Leonard, the effect may be due primarily to the raised work output associated with the positive inotropic response in the active series. It seems unlikely that a gross metabolic effect could be involved.

In part these results explain the contradictory reports in the literature relating to the effect of non-toxic doses of glycosides on oxidative metabolism^{3,5}, since results from physiologically active preparations have been compared with those from inactive homogenate studies.

The expenses of this investigation were defrayed by a grant from the Life Insurance Medical Research Fund of Australia and New Zealand.

Inhibition of Active Sodium Transport by Cholera Toxin

ACTIVE transport of sodium across cell membranes is now established as one of the fundamental physiological processes of most vertebrate cells. This process probably requires some sort of carrier molecule which binds sodium and which is coupled to a source of energy, the whole being designated for simplicity as a 'pump'. Failure of sodium transport may occur because of failure of energy supply, as, for example, in ischaemic skin and muscle after injury¹. Certain drugs, such as cardiac glycosides, inhibit active transport by competing with sodium for the carrier². One might also expect to find instances of failure or abnormalities of the pump itself, particularly in disease, but no examples of this are known.

Recent work³ shows that in rat small intestine and colon, sodium is transported actively from lumen to blood, but that water transfer depends upon gradients of water activity and is a passive process. Net absorption of water, therefore, is dependent on active sodium absorption. If active sodium transport across the intestinal mucosa were decreased or abolished, one would predict the excretion of abnormally large amounts of water and sodium from the intestine, that is, diarrhoea.

This hypothesis could be tested by determining the effect on active sodium transport of crude extracts or toxins from micro-organisms which produce disease accompanied by diarrhoea. Cholera is an obvious example, and the preliminary results of such an investigation are reported here.

Experiments were carried out on abdominal skin and gastric mucosa from the European brown frog, *Rana temporaria*, and on skin from the American grass frog, *Rana pipiens*. The skin, or gastric mucosa, was fixed between two conical compartments filled with frog Ringer solution which was mixed by an air

pump. The potential difference across the tissue was measured, and in many experiments an external potential, applied through agar electrodes, was adjusted to maintain the potential difference at zero. The current produced by the untreated frog skin at zero potential (the 'short-circuit' current) has been shown by Ussing and Zerahn⁴ to be equal to the net sodium flux. Therefore this current served in preliminary experiments to indicate changes in active sodium transport. In other experiments either the influx or efflux of sodium across the skin was measured with sodium-22, while the potential difference was held at zero, as described previously⁵. The flux in either direction could then be calculated from the relationship: net flux = influx - efflux.

All experiments reported here were performed with 'Cholera Filtrate Duphar' (N.V. Philips-Roxane, Amsterdam). The material was supplied freeze-dried in ampoules. The concentrations given are $\mu\text{gm. per ml.}$ of Ringer solution in contact with the skin.

Fig. 1 shows a typical effect produced by the addition of cholera filtrate to both sides of the frog skin ($725 \mu\text{gm./ml.}$) Both short-circuit current and potential difference (measured by momentarily disconnecting the external electromotive force) decreased rapidly after addition of the cholera filtrate, a result characteristic of inhibition of active sodium transport. Fig. 1 also shows the effect of the same concentration of cholera filtrate on the potential difference and short-circuit current of the frog gastric mucosa. In this tissue only a transient increase in both occurred (possibly the effect of protein). Since the frog gastric mucosa does not actively transport sodium, this experiment indicates that the toxin is rather specific. In other experiments, similar to those

shown in Fig. 1, it was established that the minimal effective concentration of the cholera filtrate used was about $60 \mu\text{gm./ml.}$ The same effect was produced by adding the toxin to the solution on the anatomical outside of the skin only. Adding the toxin to the solution on the inside of the skin did not decrease the current or potential difference, indicating a possible effect on permeability of the outward-facing membrane.

Further experiments with skin from *R. pipiens* were made using sodium-22 as a tracer to prove that after addition of cholera toxin the decrease in short-circuit current was actually caused by decreased net sodium flux. Results from two representative experiments are given in Table 1. The influx of sodium was measured by addition of sodium-22 to the outside solution; net sodium flux was calculated from measurements of the short-circuit current; sodium outflux was calculated by difference. Cholera filtrate clearly decreased net sodium flux and sodium influx, that is, active sodium transport.

Table 1. EFFECT OF CHOLERA FILTRATE ON SODIUM FLUX ACROSS THE FROG SKIN

	Time (min)	Influx	Efflux	Net flux
Experiment 1				
Control	0-30	1.10	0.19	0.91
	30-60	1.10	0.25	0.85
Cholera filtrate	60-90	0.02	0.22	0.70
	90-120	0.44	0.12	0.32
Experiment 2				
Control	0-30	2.44	0.42	2.02
	30-60	1.99	0.27	1.72
Cholera filtrate	60-90	1.88	0.25	1.63
	90-120	1.11	0.05	1.06
	120-150	0.49	-0.09	0.58

Sodium fluxes are given in $\mu\text{mole/cm.}^2/\text{hr.}$ for successive 30-min. periods. Cholera filtrate ($650 \mu\text{gm./ml.}$) was added to the solution on the outside of the skin.

Only a few experiments have been performed to attempt to determine the nature of the component of cholera filtrate which inhibits active sodium transport. After dialysis through 'Cellophane' the active material is present in the dialysate. The activity is not measurably decreased by heating for 1 hr. at 80°C. Its properties therefore resemble those of the cholera endotoxin described by Burrows⁶, and differ markedly from those of receptor destroying enzyme⁷ (neuraminidase). Further experiments are in progress to determine the nature of the active material. The effect on sodium transport is consistent with our hypothesis for the diarrhoea of cholera.

PATHOLOGY

Influence of Hyperthyroidism and of Thyroidectomy on Induced Mammary Cancer

It has been found¹ that the intragastric administration of optimal quantities of 3-methylcholanthrene induces mammary cancer with great rapidity in females of a susceptible strain of rats under standardized conditions; all the animals have invariably developed multiple mammary cancers within two months. Sex hormones are of critical significance² in the induction of mammary cancer by aromatic hydrocarbons. The effects of hyperthyroidism and of thyroidectomy were investigated in the present work.

Female rats of the Sprague-Dawley strain were received from a dealer at age 42 days, and certain groups were subjected to ovariectomy or thyroparathyroidectomy on the same day under ether anaesthesia. The thyroidectomized rats were supplied 1 per cent calcium lactate as drinking fluid thereafter. At age 63 days all the animals were fed 3-methylcholanthrene 10 mgm., dissolved in sesame oil (1 ml.) by gastric intubation, and this was repeated semi-weekly for 7 weeks. In addition, 3-methylcholanthrene was administered similarly to a group of intact rats for purposes of control, and to two groups receiving 1-thyroxine 0.5 mgm., or 1.0 mgm., respectively, beginning at age 63 days. 1-Thyroxine was freshly prepared daily and administered intraperitoneally 6 days each week for 7 weeks. The rats were examined daily for palpable mammary cancer and each tumour was confirmed histologically. The cytology of the vagina was studied frequently by preparing vaginal smears.

Among criteria for completeness of thyroidectomy were a profound depression of body-growth (Fig. 1) and the findings at necropsy of small adrenal glands (41.1 ± 8 mgm.) and a small spleen. The spleen was approximately one-third the size of that of intact rats; the adrenal glands of the intact control rats weighed 84.6 ± 10.8 mgm. Ten of the thyroidectomized rats had regular 5-day oestrous cycles, while two animals had irregular cycles. 1-Thyroxine (0.5 mgm.) did not modify the rate of body growth. Rats receiving 1-thyroxine (1 mgm.) grew at a normal rate for 3 weeks, but body growth was retarded significantly thereafter (Fig. 1).

All normal control female rats, and those receiving 1-thyroxine (0.5 mgm.), developed multiple mammary

Table 1. INFLUENCE OF OVARIECTOMY, THYROIDECTOMY AND THYROXINE ON INCIDENCE OF MAMMARY CANCER IN FEMALE RATS FED 3-METHYLCHOLANTHRENE

	No. of rats	Rats with tumours	Appearance of palpable tumours (days)		
			Range	Median	Mean
Intact, controls	10	10	40-78	57	60.5 ± 12.1
Ovariectomized	10	3	66-127	—	—
Thyroidectomized	12	7	52-134	119	106 ± 28.5
1-Thyroxine (0.5 mgm.)	10	10	35-69	43	49.5 ± 11.6
1-Thyroxine (1 mgm.)	11	4	64-119	—	—

cancer (Table 1), which grew rapidly to a large size. Frequently the tumours attained a weight of 15 gm. by the ninetieth day of the experiment.

Ovariectomized or thyroidectomized rats and animals receiving 1-thyroxine (1 mgm.) had a significant decrease in the incidence of mammary cancer and a delay in their development. Only solitary cancers developed, and these remained small during observation for 6 months; the weight of the largest tumours was less than 100 mgm.

The decrease in incidence of mammary cancer in ovariectomized rats is certainly due to the deficiency of ovarian hormones. The decrease in the incidence of breast cancer in the thyroidectomized rats can be attributed to the influence of the consequent smaller calorie intake, which has been shown to have marked effects on the genesis of spontaneous and induced tumours^{3,4}. In the case of rats receiving large amounts of 1-thyroxine some other mechanism is more likely. It was of interest that ovarian function was preserved in most of the thyroidectomized rats despite the depression of the rate of body-growth.

Myxomatosis in a Californian Brush Rabbit (*Sylvilagus bachmani*)

SINCE myxomatosis was first reported near San Diego in 1930^{1,2} there have been sporadic outbreaks of the disease in commercial rabbitries along the coast at least as far north as San Francisco. Sharp outbreaks of a disease highly lethal for European rabbits (*Oryctolagus cuniculus*) have been interspersed with long quiescent periods; a pattern which suggests that the disease is maintained elsewhere than in European rabbits used for commercial purposes. Although it has been suggested^{2,3} that wild rabbits (*Sylvilagus* spp.) might be the reservoir, this has never been demonstrated.

Two simultaneous outbreaks of myxomatosis were reported in California during August 1959. One of these was at Palo Alto, 40 miles south of San Francisco, and the other was in commercial rabbitries between Vista and San Luis Rey, near San Diego.

The outbreak at Palo Alto was confined to one group of eight pet European rabbits, and a single rabbit in a group of seven on a neighbouring property. There are no commercial rabbitries in this semi-rural residential area, although there are several small colonies of pet rabbits scattered through the district. There appeared to be no connexion between this outbreak and the larger one in southern California.

Three brush rabbits (*Sylvilagus bachmani*) were trapped in the immediate vicinity of the affected colony at Palo Alto. One of these had a small and rather dry tumour on its left foreleg. This was removed aseptically and stored in sterile 50 per cent glycerol. Afterwards it was ground in a chilled mortar and suspended in calf serum saline containing antibiotics. An aliquot of 0.8 ml. of the approximately 10 per cent suspension was inoculated intradermally at several sites on the plucked flank of a domestic rabbit (*Oryctolagus cuniculus*). Small palpable nodules were detectable at the sites of inoculation on day 3, and these had merged into a flat plate-like tumour by day 5. The rabbit died on day 9 displaying typical but subdued symptoms of myxomatosis; a syndrome characteristic of the disease produced by the Californian prototype strain³.

The sera of all three brush rabbits contained complement-fixing antibodies against myxoma antigen; the serum of the infected rabbit having a titre of 1/320. The antigen used in these tests was prepared with a strain of myxoma virus recently recovered during an outbreak in laboratory rabbits in Panama. This strain causes symptoms similar to the classical South American strains (for example, Brazil/Campinas/1949/1-Lausanne)³. The sera of sixteen brush rabbits trapped several miles from the outbreak area were negative.

This demonstration of the occurrence of infection with myxoma virus in wild *Sylvilagus bachmani* lends considerable support to the view that myxomatosis is enzootic in the wild rabbits of California, and it seems likely that the sporadic outbreaks of the disease in commercial rabbitries are due to transmission by mosquitoes from this reservoir. It will be recalled that this pattern is similar to that demonstrated by Aragao⁴ for myxomatosis in South America, where the reservoir host is the tapeti (*Sylvilagus braziliensis*).

Observations made at both outbreak areas and results of current experiments on transmission and immunology of myxomatosis in brush rabbits are being prepared for publication elsewhere.

These investigations were aided by a grant from the Wool Research Committee of the Commonwealth of Australia.

BACTERIOLOGY

Brucella Bacteriophage

PARNAS *et al.*^{1,2} obtained 14 samples of *Brucella* bacteriophage from old cultures of *Brucella abortus* and compared with these a *Brucella* phage originally isolated from manure in the U.S.S.R. The phages were described as being round, elementary bodies 60–80 mμ in diameter but with no tail. Cultures of *Br. abortus* were lysed by the phage, but cultures of *Br. suis*, *Br. melitensis* and a non-typical *Br. abortus* strains were not lysed. These observations have been confirmed by other workers^{3,4}.

A sample of the bacteriophage was received from Poland (through the courtesy of Dr. M. Kaplan, World Health Organization, Geneva). Originally, the phage was propagated by addition to young, actively growing cultures of *Br. abortus* strain 544 in Albimi broth but, later, a preparation with a much higher titre was prepared by the double layer method⁵. The phage was suspended in 0.033 M phosphate buffer containing 0.002 M magnesium, 0.00025 M calcium and 1/10,000 albumin⁶. Assay of this material on *Br. abortus* 544 gave a value of 2.8×10^{10} plaque-forming particles/ml. Two kinds of plaques were found, one being 2.5 mm. in diameter and the others being 0.1–0.5 mm. in diameter (Fig. 1). Repeated subculture of single small and large plaques still gave rise to a mixture of small and large plaques.

Fig. 1. The different kinds of plaques on *Br. abortus* 544

For phage typing, *Brucella* cultures were grown on serum dextrose agar for 24–36 hr. and the growth suspended in buffered saline. A loopful of the suspension was cultured on well-dried, serum dextrose agar plates and 0.02 ml. of the phage preparation, at the routine test dilution of 10^{-3} , spotted on the culture. Readings were taken after 24 and 48 hr. of incubation. All cultures of *Br. abortus* (including those of type II Wilson) were lysed but none of 4 cultures of *suis*. However, of 33 cultures of *Br. melitensis* studied, 24 were lysed by the phage preparation. All the *melitensis* cultures that were lysed had been isolated in Great Britain—mostly from bovine milk samples.

In another experiment, the phage preparation was titrated using *Br. abortus* strain 544 and *Br. melitensis* strain H (isolated in Britain) as host cultures. The value against *abortus* was 2.8×10^{10} plaque-forming particles/ml. and against *melitensis* 9×10^9 plaque-forming particles/ml. Therefore the *Brucella* phage is able to lyse not only *Br. abortus* but also some strains of *Br. melitensis* as well.

For electron microscopy, the phage was washed in 0.033 M phosphate buffer containing 0.00025 M calcium chloride and examined by the negative contrast method⁷. The phage particles were polyhedral, 65 m μ across, hexagonal in plan view and bore a wedge-shaped tail, 14 m μ long, attached to one corner (Fig. 2). They are indistinguishable from *coli* phage T3 (Bradley, D. E., and Kay, D., unpublished work) and are believed to be the first example of this morphological type outside the *coli*-typhoid group of phages.

Fig. 2. *Brucella* bacteriophage. Negative contrast preparation with phosphotungstic acid

Sensitivity to Dihydrostreptomycin of Enterobacteriaceae Strains on Media containing Ammonium

IN the course of investigations of the fertility of some strains of Enterobacteriaceae, it was observed that *Citrobacter* (*E. freundii*) strains grew well on minimal medium plates supplemented with galactose 1 per cent and dihydrostreptomycin 100 μ gm./ml. On the same medium, *E. coli* strains showed no growth. The *Citrobacter* strains were isolated during 1942-43 before the 'streptomycin era'. On complete medium with the same amount of dihydrostreptomycin, both *Citrobacter* and *E. coli* strains were completely inhibited. Even though an explanation of this phenomenon has not been reached as yet, a brief report on the results obtained so far will be given here.

The minimal medium was 'EMS', which contains ammonium sulphate as nitrogen source, magnesium sulphate, sodium chloride, dipotassium hydrogen phosphate, succinate, eosin methylene blue as indicator, and in this case galactose 1 per cent in addition. 'EMB', which was the complete medium used, contains peptone 1 per cent, dipotassium hydrogen phosphate, indicator and galactose 1 per cent. Plates were inoculated with one drop of a suspension (about 10^8 cells/ml.) in saline of a 20-hr. broth agar plate culture. The plates were read after 48 hr. at 37° C.

Table 1 shows the results of sensitivity tests on 'EMS' and 'EMB' medium supplemented with 100 μ gm./ml. dihydrostreptomycin. A number of Enterobacteriaceae strains belonging to the biochemically defined genera *Salmonella*, *Arizona*, *Klebsiella* and *Cloaca* are included. Some *Shigella*, *Proteus*, *Providencia*, *Hafria*, *Morganella* and *Rettgerella* strains were also examined, but, as many of these grew only poorly or not at all on minimal medium, results with these strains are not recorded in Table 1. It appears that almost all *E. coli*, *Klebsiella* (and *Cloaca*) strains were sensitive to 100 μ gm./ml. dihydrostreptomycin on both complete and minimal media. In contrast, all the *Salmonella* and practically all the *Citrobacter* strains were resistant to dihydrostreptomycin when tested on 'EMS' (minimal) medium, while the same strains were sensitive on 'EMB' (complete) medium. Some of the few *Arizona* strains examined were resistant and some were sensitive on 'EMS' streptomycin medium. In this connexion, it should be noted that the four *Arizona* strains that were streptomycin-resistant on 'EMS' medium were diphasic. None of the six streptomycin-sensitive strains was diphasic.

As mentioned above, the suspensions used for inoculation were made in distilled water from broth agar plates incubated at 37° C. for 20 hr. The results were the same when the inoculation suspen-

Table 1. RESISTANCE OF ENTEROBACTERIACEAE STRAINS TO DIHYDROSTREPTOMYCIN ON MINIMAL AND COMPLETE MEDIA

	No. of strains	'EMB'		'EMS'	
		R	S	R	S
<i>Salmonella</i>	25	0	25	25	0
<i>Citrobacter</i>	31	0	31	26	5
<i>Arizona</i>	10	0	10	4	6
<i>E. coli</i>	205	0	205	0	205
<i>Klebsiella</i>	63	0	63	0	63
<i>Cloaca</i>	7	0	7	0	7

All media contain dihydrostreptomycin 100 μ gm./ml. R, Growth; S, no growth. Strains which were streptomycin-resistant were excluded.

sions were prepared from minimal medium plates ('EMS' galactose).

Table 2 gives the results of sensitivity tests on 'EMS' and 'EMB' media supplemented with galactose and varying concentrations of dihydrostreptomycin, using strains selected at random from different genera of Enterobacteriaceae. It will be seen that the phenomenon described above for *Citrobacter* strains seems to be common for bacteria belonging to Enterobacteriaceae, that is, when high resistance to dihydrostreptomycin is found on minimal medium, a comparatively high, but in absolute figures much lower, resistance is found on complete medium. This also means that it is possible for all genera of Enterobacteriaceae to find a concentration of dihydrostreptomycin which will inhibit all growth on 'EMB' medium, while the same concentration on 'EMS' medium will have no visible effect on the growth. The level at which inhibition occurs varies between the different genera, and is exceptionally high for *Salmonella* and *Citrobacter*.

Table 2. INHIBITORY CONCENTRATIONS OF DIHYDROSTREPTOMYCIN ON COMPLETE AND MINIMAL MEDIA

Genus	Strain	'EMB'	'EMS'
		Dihydrostreptomycin ($\mu\text{gm./ml.}$)	Dihydrostreptomycin ($\mu\text{gm./ml.}$)
<i>Salmonella</i>	4066*	128	8,192
<i>Citrobacter</i>	Ballerup 1	16	2,048
<i>Arizona</i>	Arizona origin	<2	32
<i>E. coli</i>	K1	<2	32
<i>Klebsiella</i>	K20	<2	16
<i>Cloaca</i>	8127/51	4	32

* *S. typhi* murium.

Tests were read after 48 hr. at 37° C. The figures indicate the plates with the lowest concentration of dihydrostreptomycin which showed no growth. The plates contained two-fold dilutions of dihydrostreptomycin from 2 $\mu\text{gm./ml.}$ to 8,192 $\mu\text{gm./ml.}$

It should be mentioned briefly that the principle described could be used for differential diagnosis between genera of Enterobacteriaceae, provided that the results can be confirmed on a larger material. Furthermore, the minimal medium described seems to act as an excellent primary selective medium for *Salmonella* and *Citrobacter* strains.

In order to ascertain which factor(s) were responsible for the great difference in sensitivity on minimal medium and on complete medium, some new media were devised. Common to these was the following basic medium called B: sodium chloride 1 gm., magnesium sulphate 1 gm., dipotassium hydrogen sulphate 2 gm., glucose 10 gm., agar 20 gm., distilled water 1,000 ml. The following additions were made: B1 = B + peptone 'Orthana' 0.2 per cent, B2 = B + casamino-acid 'Difco' 0.2 per cent, B3 = B + ammonium sulphate 0.5 per cent, B4 = B + ammonium sulphate + peptone 'Orthana' 0.2 per cent, B5 = B + ammonium sulphate + casamino-acid 'Difco' 0.2 per cent.

These five media were supplemented with dihydrostreptomycin in two-fold dilutions from 0.07 $\mu\text{gm./ml.}$ to 10,000 $\mu\text{gm./ml.}$ One *coli* strain, the test strain for O-antigen 0100, and a *Salmonella typhi* murium strain Br 4066, were tested on these media. The plates were inoculated with suspensions from 20-hr. broth agar plates in amounts which would give about 500 colonies per plate on a complete medium without streptomycin. Table 3 shows the concentrations of dihydrostreptomycin which completely inhibit visible growth on the different media. It will be seen that

the great difference in sensitivity found on B1 and B2 on one hand, and on B3, B4 and B5 on the other, can be explained by the presence of ammonium sulphate. Similar results were obtained when ammonium sulphate was substituted by ammonium chloride. It was further found that the use of 3-4-hr. broth cultures for inoculation did not change the results. The conclusion must be therefore that the presence of ammonium in the media will hinder the activity of dihydrostreptomycin to a very great extent, namely, 20-100 times more dihydrostreptomycin is necessary to inhibit growth on the minimal medium than on complete medium. This effect is not caused by differences in pH, as pH determination of the five different media just before pouring showed only variations from 6.8 to 7.4. In order to test whether dihydrostreptomycin inhibited the transport of amino-acids through the cell membrane, examination was made to see whether dihydrostreptomycin could hinder the growth of amino-acid-dependent mutants in media supplemented with the appropriate amino-acids. Three mutants of *E. coli* 0100, one histidine-dependent, one tryptophan-dependent and one leucine-dependent, were tested on B1 and B3 media supplemented by the amino-acids in question; dihydrostreptomycin concentration 2.35 $\mu\text{gm./ml.}$ It was found that at least these mutants were able to utilize the amino-acids added to the media also when dihydrostreptomycin was present.

Table 3. INHIBITORY CONCENTRATIONS OF DIHYDROSTREPTOMYCIN ON MEDIA WITH AND WITHOUT AMMONIUM SULPHATE

	Media without ammonium sulphate		Media containing ammonium sulphate		
	B1	B2	B3	B4	B5
<i>E. coli</i> 0100	0.14	0.14	9.0	9.0	9.0
<i>Salmonella</i> 4066*	50	50	5,000	5,000	5,000

* *S. typhi* murium.

The experiment was carried out as plate dilution test. Figures indicate the lowest concentration of dihydrostreptomycin in $\mu\text{gm./ml.}$ which will completely inhibit growth.

It would appear that dihydrostreptomycin interferes with the availability of nitrogen when this is present as amino-acids or more complex compounds. When the micro-organisms are able to utilize ammonia, the presence of ammonium salts will render the bacteria resistant to very high doses of dihydrostreptomycin.

BIOLOGY

Cover on River Bottoms

IN a previous communication¹, C_v was defined as the area of bottom covered by stones in a given area of stream bed. It was also suggested that this concept could be expressed as the ratio of the covered bottom to the sample area and written as a fraction varying from 0 to 1. The same term cannot, however, be used for both measure of the area and the fraction, and it is therefore proposed to restrict the term C_v to the prior definition so that C_v is expressed as an area. The term C_{vf} is proposed for the fraction covered

bottom/sample area and could be conveniently referred to as the 'cover fraction'.

Tolerance to Maternal Skin Grafts in Rabbits induced by Hyaluronidase

VASCULARIZED transplants are permanently successful only between identical twins or within a highly inbred strain. Even homografts from the mother to her litter are destroyed by the immunological process initiated by her transplant antigens¹. However, tolerance for individual specific transplant antigens can be produced by the direct injection of donor cells into the foetal or neo-natal animal¹. These offspring accept grafts of normal tissue from the antigen donor. In contrast, uninjected control animals reject similar homologous transplants.

This report describes a biochemical method for the production of tolerance to maternal tissues by the intravenous injection of hyaluronidase into the pregnant rabbit. Presumably, the hyaluronidase alters permeability relationships so that the specific transplantation antigens pass from the pregnant rabbit to the litter.

Sixteen pregnant rabbits were given a single intravenous dose of 15–45 turbidity reducing units of hyaluronidase ('Infiltrase', Armour Laboratories, Chicago 11, Illinois). They were injected at 10–27 days after an observed coitus (Table 1). The gestation period in these outbred albino rabbits is 31 days. Nine litters from the injected mothers, a total of 44 progeny, were available for grafting when they were about 12 weeks old. Several rabbits failed to produce offspring, and some of the young died soon after birth.

Full-thickness skin grafts from the mother were applied to sites on the ears of the offspring. These transplants were about 3 cm. in diameter and were held in place with silk sutures. The grafts were observed daily. Rejection of a graft began with hyperemia and oedema and was followed within 24 hr. by the formation of a hard dry scab. The initial hyperemia was taken as the end-point of graft survival. All the control grafts were clearly devitalized by the fifth to the seventh day (Table 1). To eliminate the possibility that our sample of 10 controls might not adequately represent the total population we have assumed that only grafts remaining intact for more than 12 days demonstrate a significantly prolonged survival.

The experimental results (Table 1) indicate that intravenously injected hyaluronidase produces tolerance in the 11–19 day period of gestation. The progeny from animals injected on the tenth or after the twenty-second day of pregnancy failed to show a significant degree of tolerance to skin grafts. The best results thus far obtained are in the 11–15-day interval of foetal development. Eight of the 15 young from pregnant mothers injected during the 11–15-day period of gestation showed significant prolongation of graft survival. One graft is still viable at 40 days and even shows some hair growth.

Of 44 experimental animals, 19 died during the course of these experiments. They are indicated by

Table 1. SURVIVAL OF SKIN GRAFTS FROM MOTHER TO OFFSPRING FOLLOWING THE INTRAVENOUS INJECTION OF HYALURONIDASE INTO THE PREGNANT RABBIT

Exp. No.	Days of pregnancy at injection	Dose of hyaluronidase (turbidity reducing units)	Graft survival* (days)

11	27	45	7

* Each figure is for a single member of the litter. The italicized values are for animals that died within 24 hr. of their last observation. The > sign indicates that the graft was in good condition at the time of death.

italicized numbers in the last column of Table 1. The cause of death has not been established. Only an occasional animal with stunted growth was observed.

The pregnant mothers appeared unharmed by the low dose of hyaluronidase, 15–45 turbidity reducing units. The injection of 150–450 turbidity reducing units did not produce toxic effects in a few acute experiments.

Fig. 1 shows a microscopic section of a graft taken from experiment 6. This graft has good survival of all cell layers at 21 days. There is a mild infiltrate of lymphocytes.

Billingham, Brent and Medawar¹ tested 29 rabbits from four litters with grafts from their untreated

Fig. 1. Tissue section from a maternal skin graft 21 days after transplantation (Exp. 5, Table 1). All the cell layers are in good condition. A mild infiltrate of lymphocytes is present. (Haematoxylin and eosin, $\times 90$)

mothers. None of the grafts survived for more than 12 days. These results, which we have confirmed in our control experiments (experiments 1 and 2), indicate that sufficient individual specific antigen to produce immunological tolerance normally does not pass from mother to foetus. However, maternal tolerance has been produced in rats by Lengerova², who irradiated animals on the fifteenth day of their pregnancy. Despite many foetal deaths, enough of the progeny survived to demonstrate immunological tolerance to their mother's tissues.

Porter³ has recently demonstrated by direct injection that the twenty-second day of development in the foetal rabbit represents the end of the period for production of tolerance. Our results also indicate that maternal tolerance terminates at this stage. The present preliminary results further show that maternal tolerance can be obtained by the intravenous injection of hyaluronidase as early as the eleventh day of foetal development.

This work was carried out during the tenure of an Advanced Research Fellowship of the American Heart Association by one of us (P. N.). It was supported in part by grants from the Josiah Macy, Jr. Foundation and the U.S. Public Health Service (A-2938). We are grateful to Dr. Frank Fremont-Smith for his warm encouragement of this research. We acknowledge with thanks the technical assistance of Barbara Bouldin.

A Gular Plate in *Albula vulpes* (L.)

THE Elopidae and Megalopidae are considered to be the most primitive families of teleosts chiefly for three reasons: (1) the presence of an unpaired gular plate; (2) the presence of a true ethmoidal commissure between the infra-orbital sensory lines of both sides¹; (3) the conditions with regard to the skeleton of the caudal fin². In addition it may be mentioned that the Elopidae still possess a bucco-hypophysial canal (in the parasphenoid)³ and that in the Megalopidae there persists a conus arteriosus with two rows of valves. The latter primitive character is also encountered in *Albula vulpes* (L.), which has therefore also been regarded as a primitive teleost.

According to Ridewood⁴ and statements in modern text-books (for example, Berg⁵) *Albula vulpes* lacks an unpaired gular plate. In order to examine this condition, I stained a head of the latter species (Grenada, West Indies, June 28, 1955) in alizarine. By removing the skin rostral to the branchiostegal rays I then found immediately below the corium a long, narrow, median bone plate (Fig. 1) which beyond question is a gular plate at a more advanced stage of reduction than the corresponding plate in *Elops* and *Megalops*. The detection of this plate naturally does not mean that *Albula vulpes* would have a closer relationship to the Elopidae and Megalopidae than what has so far been assumed, for as is clear from other facts, *Elops*, *Mega-*

Fig. 1. *Albula vulpes* (L.). Head viewed from the ventral side. (2/3 nat. size)

lops, and *Albula* all represent evolutionary lineages of their own.

Variations in the Serum Specificities of Higher Primates detected by Two-Dimensional Starch-Gel Electrophoresis

THE proteins of human serum subjected to two-dimensional zone electrophoresis, a combination of filter-paper and starch-gel electrophoresis, can be resolved into at least 21 distinct components^{1,2}. Some of these proteins, for example, haptoglobin and transferrin, were found to be made up of components which exhibit genetically controlled variations in the human population¹⁻³. To enlarge our view of the evolutionary process underlying such variability in serum specificities, we began a comparative study of the distribution of protein components in the sera of the Primates. So far, sera from 13 chimpanzees, 19 cynomolgus monkeys, 17 rhesus monkeys, and several other macaques in addition to human sera have been analysed by two-dimensional zone electrophoresis in a discontinuous system of buffers^{4,5}. This communication reports on the results gathered up to now which enable us to distinguish the four primate groups and which emphasize a taxonomic gradation in the differences among the sera examined.

Examples of the typical starch-gel patterns of human, chimpanzee, rhesus and cynomolgus sera are shown in Fig. 1. It can be noted that each pattern has its own characteristic constellation of components. The human and chimpanzee patterns show remarkable similarities in respect to prealbumin, albumin, α -1 globulins (especially the presence of orosomucoid in the chimpanzees) and the fast moving α -2 globulins.

Fig. 1. Two-dimensional starch-gel electrophoresis of higher primate sera. The typical results in the four primate groups are represented diagrammatically. In addition, a photograph of the serum pattern of the rhesus monkey with the two transferrins is also presented.

However, the two Hominoidea differ in the following way: the transferrin of the chimpanzees migrated more slowly on filter paper than the transferrin of the humans, and the α -2 macroglobulin ($S_{\alpha-2}$) of the chimpanzees migrated more rapidly than the human protein. The amount of gamma globulin in the chimpanzees always exceeded the amount found in humans.

The starch-gel patterns of the macaques (cynomolgus and rhesus) could be distinguished from those of the humans and chimpanzees in several ways. For example, the prealbumin could barely be detected and the amount of albumin was not as large. Perhaps the clearest diagnostic feature of the macaque patterns was the absence of a fast-moving α -1 globulin of orosomucoid mobility, and the presence of a new component which has the filter paper mobility of a γ -1 globulin but in starch-gel migrates faster than gamma globulin and slower than transferrin.

The closer taxonomic relationship of the cynomolgus and rhesus monkeys to each other than to any of the other primates is clearly reflected in the starch-gel patterns. Whereas a number of features in the patterns distinguish the macaques from the higher anthropoids (as we have indicated above), very few features distinguish the sera of *Macaca* (cynomolgus) from *Macaca* (rhesus) *mulatta*. In respect to the intragenetic differences, we observed that the cynomolgus sera always had a much larger quantity of gamma globulin.

Furthermore, in our limited sampling, the rhesus monkeys showed more intraspecific variation in serum pattern than the cynomolgus monkeys. An example of this is presented in Fig. 1e, in which a second transferrin can be seen to be directly ahead of the first by both the filter paper and starch-gel separations. This result confirms the observation of Bangham and Tee, reported by Allison⁶, of a β -globulin variation among rhesus monkeys. In our work 10 of the 17 rhesus sera showed the additional component in contrast to the 19 cynomolgus sera which only showed the one transferrin. It is of interest

that the rhesus monkey occupies a broader ecological habitat than the cynomolgus, and because of this, one is tempted to speculate that between the two species the rhesus will show more examples of polymorphism. Obviously, extensive surveys in natural populations will have to be conducted before conclusions of this type in respect to the Primates can be arrived at.

The identity of the various components was established by immunochemical methods, of which immunoelectrophoresis⁵ was particularly suitable. For this purpose, we employed rabbit antisera (supplied by the Behringwerke, Marburg, Germany) to human γ -globulin, transferrin, α -2 macroglobulin, albumin, and prealbumin⁷. We also employed chicken antisera against the same proteins and against orosomucoid⁸. The primate sera belonged to the collection gathered for a previous study⁹. It is again a pleasure to thank Drs. G. D. Brigham, Sidney Gaines, Albert B. Sabin, and George B. Rabb for providing these samples. The generosity of Prof. H. E. Schultze in having portions of his highly specific rabbit antisera sent to us is also appreciated. This research was supported by the National Institutes of Health, National Multiple Sclerosis Society (U.S.A.), and Children's Fund of Michigan.

Metabolism of D-Xylose by Moulds

THE filamentous fungi have been called ubiquitous and omnivorous, and certainly they are widely distributed in Nature where they play a most important part in the decomposition of complex organic matter and as pathogens for many plants. Since much of the plant-derived organic matter in Nature contains a large amount of pentoses, mostly in the form of pentosans, a study of the pentose metabolism of the fungi which decompose this material is of interest not only because it is a basic phenomenon, but also, as we have found, because it is somewhat unique.

Early work on the fermentation of D-xylose-1-¹⁴C by the resting cells of *Fusarium lini* Bolley suggested a dissimilation similar to that in *Lactobacillus pentosus*¹; namely, the conversion of the D-xylose to equimolar quantities of carbon dioxide, ethanol and acetic acid presumably following a split of the molecule into a C₂ and a C₃ fragment. Another aspect of pentose metabolism in filamentous fungi is the formation of mycelial glucosan from pentoses labelled with carbon-14 by an unknown pathway in *Aspergillus niger*². Indeed, there is but little information

on the enzymatic sequences and intermediates of pentose metabolism in any of the fungi. In contrast, recent intensive studies on the metabolism of pentoses by various bacteria have revealed two common features in the sequence of intermediates. Metabolism is initiated with the conversion, by the appropriate isomerase, of the aldopentose to the corresponding ketopentose; specifically D-xylose and L-arabinose are converted to D-xylulose and L-ribulose respectively³⁻¹¹. The second feature common to the utilization of the pentoses is the conversion of the ketopentose to the important intermediate D-xylulose-5-phosphate. This is accomplished by the phosphorylation of the ketopentose followed by epimerization to D-xylulose-5-phosphate^{12,13}. The latter intermediate is further metabolized by well-established pathways.

During the course of work in this laboratory on D-xylose metabolism by cell-free extracts of *Penicillium chrysogenum* an enzymatic sequence was found for the interconversion of pentoses which is quite different from that in the bacteria. Instead of being converted to the corresponding ketopentose, D-xylose is reduced rapidly to D-xylitol by a triphosphopyridine nucleotide-linked reductase, followed by oxidation of the D-xylitol to D-xylulose or L-xylulose with a diphosphopyridine-linked dehydrogenase. Whether D- or L-xylulose is formed depends upon whether the C₂ or C₄ carbon is oxidized, since xylitol is symmetrical^{14,15}. When the mould is grown on L-arabinose a similar enzymatic mechanism converts this pentose to L-ribulose and L-xylulose with the formation of L-arabitol as an intermediate¹⁶.

To determine how general this metabolic pattern is among micro-organisms a study was made on fourteen species of moulds and yeasts selected from nine genera according to their ability to grow on D-xylose as the only carbon source and their common occurrence in Nature. The cultures were transferred twice on a xylose-mineral salts-agar slant and spores from the second slant were inoculated into the same medium minus the agar¹⁵. This synthetic medium was not the best for all the fungi; however, sufficient growth occurred after 72 hr. on a rotary shaker so that

the cells could be harvested for the preparation of cell-free extracts. The enzyme preparation from yeasts was made by breaking the cells with small glass beads in a 10 kc./s. sonic oscillator and from the moulds by grinding a washed sand-cell mixture in a chilled mortar. Table 1 gives the experimental details and the results of this general survey. The xylitol and xylulose produced by the fungi listed in Table 1 were further identified by paper chromatography.

It should be pointed out that no attempt has been made to obtain maximum activity for any of the organisms and that the specific activities cannot be associated with the amount of growth on D-xylose in this particular medium. All the *Aspergillus* species grew luxuriantly on D-xylose and showed low specific activity for xylose reductase, whereas *Myrothecium verrucaria* grew comparatively less and showed the highest specific activity. A possible explanation of the variation in xylose reductase activity is that the glucose-6-phosphate is susceptible to phosphatases and consequently the triphosphopyridine nucleotide reducing system is destroyed. This was quite apparent with the *Neurospora crassa* experiments where considerable free glucose was evident on the paper chromatograms that were used to separate D-xylose and xylitol. With the exception of *Neurospora crassa* and *Myrothecium verrucaria*, the rate of reduced diphosphopyridine nucleotide oxidation in a mixture of D- and L-xylulose was equal to the sum of the rates on each isomer alone, indicating the stereospecificity of two enzymes; this may not be true with the exceptions mentioned.

The fourteen fungi listed in Table 1 as possessing this unique method of D-xylose metabolism were the ones in the twenty which were tested that grew on D-xylose. *Escherichia coli*, *Aerobacter aerogenes*, *Bacillus subtilis*, *Bacillus cereus*, and *Pseudomonas aeruginosa* grew well in a medium with D-xylose as the only source of carbon, but their cell-free extracts were devoid of the reductase. It seems that this unique pathway for the metabolism of aldopentoses is confined to filamentous fungi and yeasts, thus

Table 1. SPECIFIC ACTIVITIES OF XYLOSE REDUCTASE AND XYLITOL DEHYDROGENASE IN CERTAIN FUNGI GROWN ON D-XYLOSE*

* All the activities are corrected for endogenous reactions.

† The assay system contained 30 μ moles glucose-6-phosphate, 0.2 mgm. glucose-6-phosphate dehydrogenase, 1 μ mole triphosphopyridine nucleotide, 10 μ moles magnesium chloride, 30 μ moles D-xylose and 10 mgm. protein in a total volume of 2.0 ml. of 0.05 M phosphate buffer at pH 7.2. Incubation was at 30° for 40 min. Aliquots were analysed simultaneously for xylose and xylitol by the orcinol and periodate oxidation procedures respectively after the reaction was stopped by zinc barium precipitation. The specific activity is expressed as μ moles xylose reduced per mgm. protein.

‡ The assay system contained 40 μ moles xylitol, 20 μ moles diphosphopyridine nucleotide, 10 μ moles magnesium chloride and 10 mgm. protein in a total volume of 2.0 ml. of 0.1 M Tris buffer at pH 8.5. Incubation was at 30° for 1 hr. Aliquots were analysed for ketopentoses by the cysteine-carbazole colour test. The specific activity is expressed as μ moles ketopentose formed per mgm. protein.

§ The assays were made spectrophotometrically at 340 m μ . The system contained 0.16 μ mole reduced diphosphopyridine nucleotide, 15 μ moles of either ketopentose or both and enough enzyme protein to give a 0.1 O.D. change per min., in a total volume of 0.1 ml. of 0.1 M phosphate buffer at pH 7.5. The readings were taken after a reaction time of 2 min. The specific activity is expressed as μ moles $\times 10^3$ reduced diphosphopyridine nucleotide oxidized per min. per mgm. protein.

differentiating them biochemically from bacterial and animal cells.

A portion of this information was presented at a meeting of the Society of American Bacteriologists during May 1-5. The work was supported by grant E-1201 from the National Institutes of Health.

Structure of *Acrocomia* Fruit

Of the palm kernels utilized as feeding materials, those of the coconut (*Cocos nucifera* L.) and palm nut (*Elaeis guineensis* L.) are best known. The differences in structure of the endosperm cells probably provide the most reliable means of distinguishing between the two species in meals or cakes. The endosperm cells of the coconut are more elongated than those of the palm nut and their walls are uniformly thickened, as opposed to the pitted walls of *Elaeis*¹.

Occasionally, commercial samples are obtained under the description of Paraguayan palm. The botanical name for this plant has been given as *Acrocomia totai*. This palm is an important oil plant in Paraguay² but no descriptions have been found of the histology of the fruit. Studies of the histology of fruits and seeds can be important in plant taxonomy and are also valuable in the identification of commercial plant products.

An investigation has been carried out into the histological structure of the commercial samples of Paraguayan palm with the view of establishing some

Fig. 1. Endosperm cells of *Acrocomia*. ($\times 200$)

Fig. 2. Endosperm cells of *Cocos*. ($\times 200$)

means of distinguishing between them and samples of coconut and palm nut. To augment this material, fruits of *Acrocomia sclerocarpa* Mart. have been obtained from Brazil. This species is very closely related to *totai*³.

It has been found that, as in the case of *Cocos* and *Elaeis*, a consideration of the structure of the endosperm is most useful for the purposes of identification. Fig. 1 illustrates some typical endosperm cells of *Acrocomia* as they appear in a cleared preparation. The cells are brick-shaped, and their walls show no obvious pits. The absence of pits immediately distinguishes *Acrocomia* from *Elaeis*. In comparing the endosperm with that of *Cocos*, the shape of the cells provides the main distinguishing feature. Fig. 2 illustrates some typical *Cocos* endosperm cells. These cells are much more elongated than those of *Acrocomia*, a feature shown equally well in a longitudinal section of endosperm or a cleared preparation of a cake or meal.

It is intended to publish the details of this investigation elsewhere. I am indebted to Salamon and Seaber (consulting analytical chemists) for the supply of certain material used in this work.

Changes in Sex in the Hop caused by Plant Growth Substances

DURING an experiment to test the effects of certain systemic chemicals on the hop plant (*Humulus lupulus* L.) the production of male flowers by a genetically female plant was noticed. This behaviour may occur naturally in some varieties; but the phenomenon has not been reported in the variety Fuggles which was used in the present experiments. These were designed originally to determine whether treatment with low concentrations of certain systemic chemicals would lead to changes in the chemical composition of the plant. For this purpose plants were sprayed with aqueous solutions of a number of phenoxy and phenylthio acids which, although similar in structure to plant growth substances, were either inactive or only weakly active¹.

Three levels of treatment were given, the plants being sprayed to run-off with 500 p.p.m. solutions of each of the acids as their sodium salts either once, twice or three times, with intervals of several days between sprayings. When flower parts appeared it was observed that male flowers had only developed

Fig. 1. Production of male organs on a genetically female plant following the application of α (2-chlorophenylthio)propionic acid

on those plants which had been sprayed with solutions of α (2-chlorophenylthio)propionic acid; three plants showed this effect, not all of which had received the maximum spray treatment.

In the following year an experiment was designed specifically to test whether the stage in growth of the plant at which the spray was applied was an important factor in relation to male flower development. The spraying was carried out as before with a 500 p.p.m. solution, and in a row of about 30 plants a different plant was sprayed at two-day intervals, beginning on July 2 and continuing until the beginning of August. The plants not sprayed were left as controls.

When the flowers developed it was seen that a large number of male flowers had developed on those plants sprayed on July 2 and 4; there were fewer on the plant sprayed on July 6, and practically none on those which were sprayed afterwards. The plants sprayed on July 8 and 10 showed slight deformities of the cones, but those plants which had received the later sprayings showed no abnormal effects and could not be distinguished from the controls.

Heslop-Harrison, in reviews of conditions governing sex expression in flowering plants^{2,3}, describes changes of sex resulting from treatments with the plant growth substance 2:4-dichlorophenoxyacetic acid or with the plant growth hormone indoleacetic acid. It seems possible that the weak growth properties of α (2-chlorophenylthio)propionic acid may operate in inducing the responses reported here. In this connexion, however, it is important to note that in all cases reported previously, growth substance treatment caused a change from male to female flowering whereas the changes reported here have been from female to male.

It is of interest that the experiments quoted in the literature where sex changes appeared were carried out with short-day flowering plants; the suggestion has been made, however, that long-day plants may not follow the same pattern⁵, it having been observed that spinach tended to produce male flowers under short-day conditions.

Heslop-Harrison has suggested that photoperiodism may be related to natural auxin concentration; if this is the case with spinach, then either auxin concentration is lowered under short-day conditions or the initiation of male flowers arises from high auxin-levels. While the former possibility is unlikely, the latter supposition is difficult to correlate with the findings

that with other plants, application of growth substances leads to the formation of female flowers.

The present experimental results with hop plants throw light on this problem if it be assumed that, as long-day plants, the hop and spinach behave similarly with respect to both day-length and applications of growth substances. A distinction may then be drawn between a long-day and a short-day flowering plant; in the former, high auxin-levels might promote the growth of staminate structures whereas in the latter, high auxin levels might promote pistillate structures.

I wish to thank Prof. R. L. Wain for his guidance and encouragement, the Hop Research Department for facilities, and Mr. R. A. Neve for his valuable help.

STATISTICS

Structural Relations in Component Analysis

IN a recent communication, Hey and Hey¹ have described Berkson's postulate of the 'controlled variable' as unjustified and his mode of analysis as invalid. After correspondence with Hey and Hey, we feel that it is their criticisms that are not valid; had they been, they would have applied equally to the whole of regression theory. In particular, they do not seem to attach sufficient weight to the need for a careful specification of the reference distribution with which the observations are to be compared.

In our communication² to which Hey and Hey refer, we included Berkson's method in a list of several which can be appropriate in various circumstances; we should perhaps have stated more clearly that differing experimental conditions necessitate differing analyses, and that no one method (not even that of least squares) has overall applicability. We did point out that in some versions of the structural relations problem, the method of least squares has been shown to lead to inconsistent estimates; so that in all but the simplest cases consistency and efficiency have to be justified *de novo*.

The problem considered by Hey and Hey¹ of fitting v linear relations to a set of n -dimensional observations all subject to error is essentially equivalent to component analysis, for which see, for example, Girshick³ or Kendall⁴; and has been treated explicitly in econometric contexts, for example, by Tintner⁵.

FORTHCOMING EVENTS

(Meeting marked with an asterisk * is open to the public)

Monday, October 3

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Prof. W. B. Emery: "The Antiquities of Nubia and the High Dam".

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. G. L. S. Shackleton: "Time, Nature, and Decision".

SOCIETY OF ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. W. A. Crago: "Some Notes on Hovercraft".

Wednesday, October 5

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. J. S. Elliott and Mr. E. D. Edwards: "Synthetic Lubricants for Gas Turbines".

INSTITUTE OF INFORMATION SCIENTISTS (at Swedenborg Hall, Barter Street, Bloomsbury Way, London, W.C.1), at 6.15 p.m.—Dr. G. Malcolm Dyson: "New Research at Chemical Abstracts".*

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Scientific Papers.

Thursday, October 6

ROYAL INSTITUTION OF NAVAL ARCHITECTS (at 10 Upper Belgrave Street, London, S.W.1), at 5.15 p.m.—Mr. B. N. Newton and Mr. H. P. Rader: "Performance Data of Propellers for High Speed Craft".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Sir Hamish D. MacLaren, K.B.E., C.B.: Inaugural Address as President.

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Prof. A. A. Eddy: "The Chemistry of the Cell Surface".

Friday, October 7

BRITISH MYCOLOGICAL SOCIETY (in the Large Physics Lecture Theatre, Birkbeck College, Malet Street, London, W.C.1), at 10.45 a.m.—Meeting on "The Cereal Rusts".

INSTITUTION OF ELECTRICAL ENGINEERS, MEDICAL ELECTRONICS DISCUSSION GROUP (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Nerve Endings" opened by Dr. O. C. J. Lippold and Dr. D. B. Wilkie.

SOCIETY OF DYERS AND COLOURISTS (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Prof. C. F. Carter: "Science in Industry".

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. D. H. Hey, F.R.S.: "Some Recent Developments in Heterocyclic Chemistry".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT EXPERIMENTAL OFFICER (with at least G.C.E. in five subjects, including two (science or mathematics) at "A" level, or equivalent, and laboratory experience in chemistry or biochemistry) IN THE BIOCHEMISTRY DEPARTMENT—The Secretary, Institute of Animal Physiology, Babraham, Cambridge (October 8).

LECTURER or SENIOR LECTURER (with qualifications in educational psychology and/or history and philosophy of education, and teaching experience) IN EDUCATION at the University of Queensland, Australia—The Secretary Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, October 8).

SENIOR LECTURER IN PURE MATHEMATICS—The Registrar, The University, Leicester (October 8).

ASSISTANT LECTURER (with special qualifications in physical chemistry) IN CHEMISTRY—The Registrar, The University, Manchester (October 15).

ASSISTANT TECHNICAL OFFICER (with G.C.E. in at least five subjects, two of which at advanced level (preferably including biology), or equivalent Scottish or Northern Irish qualification), for work in biological electronics and construction of apparatus for physiological research—Head of the Department of Zoology and Comparative Physiology, The University, Birmingham 15 (October 15).

PRINCIPAL LECTURER IN PHARMACEUTICS—The Principal, College of Technology, Belfast (October 21).

CHAIR OF GEOLOGY in the University of Malaya, Kuala Lumpur—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Malaya and London, October 22).

LECTURER IN MATHEMATICS, to take the subject to pass degree standard—The Principal, Bede College, Durham (October 22).

LECTURERS or ASSISTANT LECTURERS (3) IN THE DEPARTMENT OF MATHEMATICS, University of Malaya, Kuala Lumpur—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Malaya and London, October 22).

SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree in chemistry or equivalent, and well acquainted with the application of modern techniques to the analysis of foods and feeding-stuffs including estimation of amino-acids, and preferably previous experience with tropical foods) at the Tropical Products Institute (D.S.I.R.), London, W.C.1, to take charge of the analytical work in the Food Section—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. F.658/0A (October 29).

SCIENTIFIC OFFICER (with a first- or second-class honours degree with physical or inorganic chemistry as the principal subject) IN THE DEPARTMENT OF PEDOLOGY, for work involving investigations upon soil formation processes with a physicochemical bias—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (October 29).

SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree in a science, preferably chemistry, or equivalent, at least three years appropriate postgraduate experience, a wide interest in general scientific matters, and an aptitude for administration and dealing with people) in the Information Division, D.S.I.R., H.Q., London, to assist a survey team preparing detailed reports on selected scientific subjects and to undertake comprehensive surveys of scientific and technological problems in co-operation with representative and national and international organizations—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. F.666/0A (October 29).

ASSISTANT LECTURER or LECTURER IN THE DEPARTMENT OF VETERINARY PATHOLOGY—The Registrar, The University, Liverpool, quoting Ref. CV/T (October 31).

LECTURER IN PHYSICS at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, October 31).

ASSISTANT LIBRARIAN (graduate with a professional qualification) at the University College of Sierra Leone (Fourah Bay College)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 10).

LECTURER or ASSISTANT LECTURER IN GEOLOGY at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, November 10).

ASSOCIATE PROFESSOR OF STATISTICS IN THE FACULTY OF AGRICULTURAL ECONOMICS, University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, November 11).

PHYSICISTS and RESEARCH ENGINEERS (with a first- or second-class honours degree or corporate member of a senior engineering institution, or with equivalent qualifications), for research work in the Engineering Studies Branch of the Reactor Development Division; field of research covers a very wide range of basic engineering topics, with particular emphasis on methods of extracting heat from power-producing nuclear reactors, cooled by gases, liquids and two-phased coolants—The Personnel Branch (W.340/34), U.K.A.E.A., A.R.E., Winfrith, Dorchester, Dorset (November 13).

MAY READER IN MEDICINE—The Registrar, University Registry Oxford (December 2).

READER IN SOIL SCIENCE—The Registrar, University Registry, Oxford (December 2).

ASSISTANT EDITOR (with a physics degree and a knowledge of physics literature) for Section A (Physics) of the monthly publication *Science Abstracts*—The Secretary, Institution of Electrical Engineers, Savoy Place, London, W.C.2.

ASSISTANT LECTURER or LECTURER (with an interest in vertebrate physiology) IN BIOLOGY—The Principal, Derby Training College, Utttoxeter New Road, Derby.

FELLOW IN OZONE RESEARCH in the Division of Meteorological Physics, Commonwealth Scientific and Industrial Research Organization, Melbourne, Australia, to take charge of the programme of research into the measurement of ozone distribution and the meteorological applications thereof—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingway, London, W.C.2, quoting Appointment No. 420/161.

FEMALE SCIENCE ASSISTANT (preferably recent honours B.Sc. graduate), for a three-year post in bacteriology at the Dysentery Reference Laboratory—The Director, Central Public Health Laboratory, Colindale Avenue, London, N.W.9.

GRADE B ASSISTANT IN THE DEPARTMENT OF SCIENCE TO TEACH CHEMISTRY mainly to G.C.E. "A" level and in O.N.C. courses—The Principal, Reading Technical College, King's Road, Reading.

GRADUATE (metallurgy, chemistry or physics, and preferably some language knowledge) IN THE INFORMATION DEPARTMENT, for work including abstracting, production of the Association's monthly Bulletin, answering inquiries and related matters—The Secretary, British Non-Ferrous Metals Research Association, Ruston Street, London, N.W.1.

GRADUATE RESEARCH ASSISTANT IN THE DEPARTMENT OF ZOOLOGY AND COMPARATIVE PHYSIOLOGY, to work on the physiology of tissue changes during metamorphosis in insects—The Registrar, The University, Edgbaston, Birmingham 15.

LABORATORY TECHNICIAN (with experience of working with scientific or technical apparatus), to assist in the Physics Laboratories—The Headmaster, Chatham House Grammar School, Ramsgate, Kent.

LECTURER IN ZOOLOGY: a LECTURER IN ORGANIC CHEMISTRY; and a LECTURER IN BACTERIOLOGY at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1, or The Registrar, University of Queensland, St. Lucia, Brisbane, Australia.

LECTURER (with practical experience and a good honours degree) IN FLUID MECHANICS—Prof. C. M. White, Imperial College of Science and Technology, London, S.W.7.

LINAER PROFESSOR OF ZOOLOGY—The Registrar, University Registry, Oxford.

OFFICER, Assistant Experimental Officer grade (with a degree in science or horticulture, or a diploma in horticulture), to assist in

experimental work—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick.

POSTDOCTORATE FELLOW IN THE DEPARTMENT OF PHYSICS, for work on electron resonance—The Registrar, University College of North Staffordshire, Keele, Staffs.

RESEARCH ASSISTANT (CHEMIST) IN THE DEPARTMENT OF CHEMICAL PATHOLOGY, for work on problems associated with steroid metabolism—The House Governor, St. Mary's Hospital, Paddington, London, W.2.

RESEARCH ASSISTANT (with a first- or second-class honours degree in chemistry with physiology in the final year of the honours degree) IN THE DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY—Clerk to the Governors, Chelsea College of Advanced Technology, Manresa Road, London, S.W.3.

SENIOR LECTURER (qualified to direct research) IN PHYSICS; a LECTURER (preferably with an interest in mycology, ecology or cytogenetics) IN BOTANY; and a LECTURER (preferably with qualifications in research) IN MATHEMATICS—The Clerk, Northern Polytechnic, Holloway, London, N.7.

SENIOR RESEARCH ASSISTANT (with a Ph.D. or appropriate research experience) IN THE PHYSICS DEPARTMENT—Prof. J. G. Wilson, Department of Physics, The University, Leeds 2.

TIMBER OPERATIONS OFFICER (under 50 years of age, with a university degree in forestry with at least three years practical experience in the control of timber exploitation on a large scale) in the Southern Cameroons, for the administration and management of all timber operations—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BOD.61/603/02/T.

GOVERNMENT SCIENTIFIC AND TECHNICAL ADVISORY COMMITTEES

IT is now some two years since the Prime Minister indicated in reply to a Parliamentary question that he proposed to inquire into the working of the present system of government in Britain from the point of view of easing the burden on Ministers and securing the more efficient working of Parliament. Although there have been several re-arrangements of Ministerial offices, including the appointment of a Minister for Science, no specific report or statement on the subject has yet been made to Parliament; though in reply to a Parliamentary question on November 30, 1958, it was stated that the Government is now advised by some 850 bodies of a central or national character. This is only one aspect of the problem, however, though it was discussed by Prof. K. O. Wheare in his book "Government by Committee" published in 1955, and received further attention in the wider survey by a study group of the Royal Institute of Public Administration entitled "The Organization of British Central Government 1914-1956" published in 1957.

Political and Economic Planning has now published a full-scale report on "Advisory Committees in British Government"*, based on a study made possible by a grant from the Leverhulme Trust. It is concerned solely with those advisory committees attached to departments of the central Government which are of a standing or permanent, rather than a temporary, character, and as local and regional committees are also excluded, it does not cover many of those included in the total given to Parliament in 1958. A table included in the report suggests that 484 is a more accurate figure for the purpose of this particular study, and a glance at this table should suffice to show how closely this aspect of government touches the scientist and technologist.

The assumption of new functions necessitated by broadening of the responsibilities of the Government mean that administration is no longer a self-contained system. A continuing need has developed for contact and consultation with people outside the Civil Service, and nowhere is this more important than in scientific and technical matters. This is one reason for the appointment of a Minister for Science, and the study of advisory committees is important, both for the light it throws on the means of developing effective contacts with professional groups and organized interests, and the provision of specialist and technical advice. Indeed, it is interesting to note that the Colonial Office, which appears to have led the way in setting up advisory committees of the modern type, had several such committees before the First World War, and they were all committees of experts and were concerned with scientific subjects, particularly with the development and use of scientific

knowledge to improve the conditions of living in the territories with which they dealt. Such committees were appointed because the Colonial Office at that time lacked within itself scientific experts, and it emphasizes rather than otherwise the importance of the advisory committee in considering the place of the scientist in government and the means of presenting scientific and technical advice. The Haldane Report on the machinery of government in 1918, while making no recommendations regarding the organization of advisory bodies, foresaw an important place for such bodies and considered government administration was unlikely to retain public confidence unless "it was recognized as an obligation upon departments to avail themselves of the advice and assistance of advisory bodies so constituted as to make available the knowledge and experience of all sections of the community affected by the activities of the Department". Some two decades later, R. V. Vernon and N. S. Mansergh, in their study "Advisory Bodies", noted how the Haldane Committee's recommendation had reinforced the tendency to resort to external advice in this way, especially when the Government had to enter new spheres.

The survey prepared by Political and Economic Planning would be of great interest to the scientist and the technologist merely for the way in which it displays the extent to which scientific interests are affected by this tendency. It does not describe the operations of particular bodies, though the Advisory Council on Scientific Policy, the National Advisory Council on the Training and Supply of Teachers, the Colonial Research Council, the Engineering Advisory Council and the Advisory Council on Scientific Research and Technical Development of the Ministry of Aviation are among the fifteen major bodies the membership and functions of which are outlined in some detail by way of illustration, the last-named being of special interest in that no other account of its work appears to be available. More important, however, the survey reviews in succession just those aspects of the work of advisory bodies on which it is important that there should be public understanding not only in Parliament and among the specialist bodies whence the membership of such committees is often drawn but also in the country generally. Indeed, in the absence of such public understanding, the full advantages of such an advisory system are unlikely to be reached, because informed and intelligent discussion of public policy is hindered.

Beginning with a general review, in which the extent to which many committees are concerned with research, sometimes in an administrative rather than an advisory capacity, is duly stressed, and scientific committees as such receive a special note, Political and Economic Planning considers the problems of composition which may arise and their implications, the methods of work and the functions and influence

* *Advisory Committees in British Government*. Pp. xii+228. (London: Political and Economic Planning, and George Allen and Unwin, Ltd, 1960.) 25s. net.

of such committees. The difficulty of definition is frankly recognized, particularly that of differentiating between a committee responsible for advising on research programmes or policy, and one which is required to sponsor or organize research; but the research boards of the Department of Scientific and Industrial Research, the Medical Research Council, the Agricultural Research Council, the Nature Conservancy and the Overseas Research Council are regarded as possessing sufficient authority to be treated as administrative bodies, and as such are not discussed in the report, although the Scientific Advisory Council of the Ministry of Power is included. This limits to some extent the value of the survey as a discussion of the place of the scientific expert in administration, though here a major weakness is the failure of the report to make any reference to the need to have inside the Government, both at Ministerial level and in the Civil Service, those who are qualified to interpret and assess the scientific and technical advice presented to them.

This omission is the more striking in that, in the chapter on the functions and influence of committees, the nature of the problem is otherwise fairly stated, and the increasing reliance of a Government on advanced scientific knowledge, and hence on the specialists who are able to provide it, is fully admitted. Whether the need is met by employing scientific and professional staff inside the Civil Service, or by organizing the supply of knowledge from outside, there must be administrators and Ministers capable of assessing that advice in relation to other factors involved in matters of policy. This, of course, is largely a matter of education, but, while that point is overlooked, the report stresses the importance of education in the sense that it is effected by a sound public relations policy. The report takes a somewhat optimistic view of the influence of scientific committees, especially of the Advisory Council on Scientific Policy, and attributes the advantages of the advisory committee to its more systematic procedure, the more comprehensive personal contacts which it ensures, its general convenience and stability, and the more formal commitments it produces. The report questions seriously Prof. Wheare's suggestion that the development of advisory committees has strengthened Whitehall at the expense of Parliament; rather the view is held that the increased power of Ministers and their departments is counterbalanced by their dependence on independent organizations; and advisory committees are a feature of that dependence.

The report does not advocate unlimited publicity for the work of advisory committees; the risks of such publicity as well as those of excessive secrecy are both recognized. Indeed, this chapter of the report, with its clear discussion of the factors which assist or hinder the effectiveness of advisory bodies, deserves to be studied carefully both by the individual scientist and technologist and by his professional associations. One point in particular should be noted. The scientific community, the report comments, has not so far developed the unity and cohesion displayed by some trades and professions, nor do its

political and social attitudes differ markedly from those of the rest of the populace. This may well explain the absence of professional associations of scientists or technologists from among the major nominating bodies listed as sending representatives or suggesting names for inclusion on the 484 advisory committees within the scope of the report. Even if the co-operation of scientists in the machinery of government does not become politically more important, this situation represents a serious weakness in some of the positions that may develop out of the present methods of recruitment of advisory committees.

The nature of that weakness is indicated by the title of a broadsheet "Government by Appointment" (No. 443, July 25, 1960), issued by Political and Economic Planning almost simultaneously with the report. This broadsheet reviews the practice and implications of the present system of appointments to a whole range of some 40,000 posts, from nationalized boards to regional and local bodies, many of which fall outside the scope of the report itself. Both the report and the broadsheet show that the need to secure people with particular qualities for particular jobs, and for Ministers to exercise some form of remote control over administrative bodies, has led to a new system of patronage which has come to stay, but appears to involve excessive plurality; this should be diminished if possible. The report only examines evidence of plurality from Home Office and Board of Trade committees, but there is no reason for regarding this evidence as atypical. Such plurality as exists is attributed mainly to the practice of nomination by outside organizations; and while it is not regarded as of serious proportions, it could with advantage be less.

The broadsheet suggests three principles that might guide policy in recruitment. The methods used should be, so far as possible, orderly and systematic, and should be widely known, so that nominations may come from all quarters. Within the limits imposed by the nature of the job, as great a variety of persons as possible should be appointed. Thirdly, plurality should be treated as a general problem and not considered merely in relation to a particular set of institutions. Until it has been fully examined on this basis, statements about the large numbers of people willing to give voluntary service should be treated with reserve.

Clearly, if this question of appointment to advisory committees is to be handled satisfactorily, so as to reduce plurality and establish public standards of propriety and good practice, professional associations of scientists and technologists have an important part to play. They might perhaps do more than at present to discover potential candidates among their membership, particularly in the younger age-groups, to arouse their interest in such work, possibly even to coach them or prepare them for participation. Moreover, there are other important matters to be discussed which bear alike on the effectiveness of advisory bodies and the willingness of professional men and women to serve on them; for example,

membership of any such committee may bring a scientist within the operation of the Official Secrets Act, with all its effects in his contacts and relations with professional colleagues outside the committee. Such issues are only just touched on in the report; but both report and broadsheet display a range of problems which touch the scientist and technologist closely indeed, and call for further study and independent thinking both by individuals and by their professional associations.

THEORETICAL HYDRODYNAMICS

Theoretical Hydrodynamics

By Prof. L. M. Milne-Thomson. Fourth edition. Pp. xxi+660+4 plates. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1960.) 65s. net.

THE book under review is the fourth edition of one which appeared for the first time in 1938. In the pages of *Nature* (142, 1136; 1938) I discussed a number of text-books on hydrodynamics before dealing specially with the first edition of Prof. Milne-Thomson's book. In that review I ventured to suggest that the mathematical approach to hydrodynamics followed in the book might well have been amplified by a more physical approach. That is still my view, but I must add that Prof. Milne-Thomson's book has had a resounding success during the twenty-two years that have elapsed since it first appeared. I have come across many experts, both in Britain and abroad, who have spoken very highly of "Theoretical Hydrodynamics" and of the approach adopted in the book. To that extent I misjudged the need for a comprehensive book of the kind planned and written by Prof. Milne-Thomson. Each successive edition has been amplified to some extent and has incorporated new material.

There is no unique road to the study of hydrodynamics. There is the approach of the physicist who treats the subject as a branch of physics in which there are discussed the forces which act on liquids, and which are exerted by them. There is also the approach of the engineer, who is concerned mainly with applications, though some of the modern applications of hydrodynamics to engineering are compelling experts to try to obtain a deeper insight into fundamental processes than appears to have been necessary in the past. Then there is the 'express route' to trans-sonic, supersonic and hypersonic flow, which appears to be much favoured nowadays, avoiding the gaps in our existing knowledge of subsonic hydrodynamics. Prof. Milne-Thomson has taken none of these paths—his is the road of the mathematician. Clear physical statements are transformed into mathematical assumptions, and the mathematics of hydrodynamics is developed with clarity and economy. The practical and theoretical sides of the subject are made to supplement each other, but the emphasis remains that of the mathematician. The virtue of this method is that as "a scientific theory becomes more exact, so does it of necessity tend to assume a more mathematical form", and Prof. Milne-Thomson's approach seems to have found considerable support. In 1938 his method, which is based consistently on vector methods and notation, was considered to be a departure from the traditional approach, but it is now

generally accepted and is followed by many applied mathematicians.

Chapter 1 of the book is concerned mainly with inferences which may be drawn from the 'pressure theorem' of Daniel Bernoulli, who may justly be considered to be the father of hydrodynamics—the word 'hydrodynamica' was first used by him about 1780. Chapter 2 discusses those properties of vectors which are essential for the analysis of the motion of a fluid element and for the formulation of the equations of hydrodynamics. In Chapter 3 there are discussions of the general basic properties and equations of fluid motion. Chapter 4 is concerned with the mathematical properties of two-dimensional motion in so far as they can be treated without the complex variable. Chapter 5 introduces the complex variable, and conformal mappings are treated in some detail.

Chapters 6–14 treat two-dimensional motion from the unified point of view of the complex variable. In Chapter 6 there is a discussion of streaming motion followed, in Chapter 7, by a consideration of Joukowski aerofoils, while sources and sinks are dealt with in Chapter 8. In Chapter 9 the motion of a moving cylinder is treated in detail and Chapter 10 discusses specialized aspects of conformal mapping and their applications. Chapters 11 and 12 contain important applications to the discontinuous motion of jets, currents and cavities. Chapter 13 concerns itself with the motion of vortices, and the drag associated with a vortex wake. Chapter 14 deals with two-dimensional wave motion.

In Chapter 15 the Stokes stream function is introduced, and the general motion of spheres and ellipsoids is treated in Chapter 16. In Chapter 17 Milne-Thomson derives Kirchhoff's equations in vector form. Chapter 18 discusses vortex motion in general, with special application to aerofoils of finite span. Chapter 19 gives an outline of the application of vector methods to viscous fluids and a brief description of boundary layer theory. Chapter 20, the final chapter of the fourth edition, is designed as an introduction to the theory of flow of a compressible fluid at subsonic and supersonic speeds.

The presence of well-graded sets of exercises at the end of each chapter is much appreciated by many of those who teach hydrodynamics to mathematicians in British universities. The appearance of the book is clear and attractive, and the text is lavishly illustrated with line drawings and photographs which have been chosen with discretion.

Prof. Milne-Thomson's book has stood the test of time and has, in fact, been accorded increased recognition with each successive edition. Within the limitations which Prof. Milne-Thomson set himself, and which are clearly stated in the preface, his book on theoretical hydrodynamics may be described as being 'of the first water'.

L. ROSENHEAD

LOGIC AND SCIENCE

An Introduction to the Logic of the Sciences

By R. Harré. Pp. viii+180. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1960.) 21s. net.

THIS is a very welcome book. It should be said at the outset that the author's intention to write largely for undergraduates in science may prove a little on the modest side, since many students working for higher degrees would probably produce

substantially better theses if they could find time to read what Dr. Harré has to relate.

Part I deals with scientific discourse, and Part 2 with discovery and confirmation. Translated into working terms, this means a discussion on the place and understanding of 'models', followed by a thorough drilling in the reasons why laws and theories come to be accepted or rejected as the case may be. In the latter context, the author adopts a sound *via media* in his warning against premature jettisoning of a theory which may, indeed, be inadequate, but perhaps for instrumental reasons. Returning to the role of models in theoretical physics, the dangers of taking them too literally are partly due to giving excessive weight to what scientists say, rather than to what they do. In the light of history, the Rutherford-Bohr planetary atom served its generation well, and signified effectively what happened in the Cavendish Laboratory; but nobody could seriously have thought that the particular imagery would last. Yet, the grand point is that—from the aspect of discovery—disciplined insight came first, and the application of mathematical analysis afterwards. Essential as the latter is, momentous advances usually begin with remarkably simple premises. Incidentally, Max Planck is known to have fought hard and long in his mind against the consequences of his own quantum concept. The statistical and indiscriminate nature of much of modern physics was not to his liking. But that is the penalty of greatness. Questions like these are ably handled by Dr. Harré, and the moral is driven home.

Towards the end of the volume, some finer points of procedure are illustrated in the chapters dealing with "fitting the facts", and "non-factual criteria". In the first of these, the development of van der Waals' equation out of Boyle's law is treated epistemologically. It is highly important in showing the student that if he performs his experiment $pV = \text{constant}$ properly he ought to find discrepancies, and that these are due to his working with *real* gases.

The other matter is quasi-aesthetic, namely, the place of 'elegant' proofs in science. It is suggested that the inclusion of some ingenious device is needed for satisfaction of this kind. Maybe it is; but the most sublime thought can be 'symmetrical' and 'well-rounded' rather than 'angular', and this may have something to do with it. In the greatest minds, these qualities are undoubtedly revealed, and, fascinating as the subject is, we may well have to leave it at that.

F. I. G. RAWLINS

A NEW LUNAR ATLAS

Moon Maps, with a Chart showing the Other Side of the Moon based upon Soviet Photographs
By H. P. Wilkins. Pp. 36+27 maps. (London: Faber and Faber, Ltd., 1960.) 30s. net.

WHEN H. P. Wilkins died, on January 21, 1960, the astronomical world lost one of its most dedicated selenographers. His last undertaking was the preparation of a lunar atlas designed for use at the telescope. These new "Moon Maps" are based on an earlier set published in his volume "The Moon" (in collaboration with Patrick Moore, 1955), which is undoubtedly familiar to amateur lunar observers.

The accompanying text is limited to a gazetteer in which all named features, indexed alphabetically,

are described briefly and keyed to the corresponding maps. The latter are reproduced on a scale of 55.4 miles to the inch and are therefore approximately 40 per cent larger than those in the 1955 volume. The entire visible surface of the Moon is covered in 25 sections. In addition, the area surrounding the walled plain of Ptolemaeus is shown on a larger scale, and a map of the far side has been prepared from the photographs obtained in October 1959 by means of *Lunik III*.

The most unusual feature of the atlas stems from its very imaginative binding. Whereas the pages of text are spiral-bound in the conventional way, the maps are attached to the outer edge of the back cover, thus allowing the reader to place side by side any page of the gazetteer and any chosen map.

It is unfortunate that the author's failing health evidently prevented him from giving the book a final critical review before it went to press; but the few obvious omissions are by no means irreparable. In particular, the enlarged map of Ptolemaeus (Plate XXVI) bears no title and the word Ptolemaeus itself does not appear anywhere on the page; since Plate XXVI is not indexed in the gazetteer and is mentioned only briefly (by the anglicized name Ptolemy) in the introduction, this very useful map is apt to be overlooked by the casual reader.

The key chart, which appears on p. 47 of "The Moon", is absent here and would be a welcome addition, especially because the co-ordinates of the new maps are printed in type so small as to be nearly illegible in the dim light of a telescope dome. The names of the features are rather inconspicuous, too. This is of course necessary for preserving the many fine details which otherwise would have been obliterated; but these formations could be located more easily if approximate co-ordinates had been included in the gazetteer.

In spite of these few shortcomings, "Moon Maps" should be nevertheless a valuable addition to the reference shelf of the amateur observer for its abundance of minute details not readily available elsewhere.

SIMONE DABO GOSSNER

NEW APPROACHES TO DYNAMICAL ASTRONOMY

Introduction to the Mechanics of the Solar System
By Rudolf Kurth. Pp. ix+177. (London and New York: Pergamon Press, 1959.) 42s. net.

THE study of the dynamics of the solar system, which until a few years ago appeared to be almost in abeyance, has recently shown signs of a renewal of interest. This was in large measure initiated by the development of high-speed automatic computers, vastly accelerating the large amounts of numerical calculation intrinsically associated with the subject, and has been augmented by the launching of artificial satellites and space probes, which have brought new problems in dynamical astronomy with them. As a consequence there is a need for introductory books to the subject, one or two of which have appeared in the past few years, and it is into this category that this book falls.

The general approach of the book is empirical, and its simple and direct treatment (making use of vector notation throughout), as well as the inclusion of elementary explanatory material in the first chapter,

will make it of great value to those making their first acquaintance with the subject, even if they have little or no previous knowledge of the composition of the solar system, the planetary motions, or even of Newton's laws of motion and of gravitation. The first chapter shows how Kepler's laws of planetary motion may be arrived at inductively from the observations, and discusses the solution of Kepler's equation, with some analytical results. The second chapter examines the notion of force, laying down postulates for it, deriving the inverse square law, and obtaining the general solution to the general two-body problem. This chapter also contains a brief but clear description of the bases of Laplace's and Gauss's methods of orbit determination. Chapter 3 is concerned with the many-body problem, in several of its aspects. In Section 4 there is an unusual and instructive derivation of the time derivatives of the orbital elements in terms of the components of the disturbing force, based on Poisson's method of variation of parameters. (The fact that the expression for the acceleration is analytic in the time does not resolve the question of the convergence of the first-order perturbations, as suggested in Section 2.2, since the relevant radius of convergence may be very small, and in fact some modern work suggests that it is so.) Chapter 4 deals with the oblateness problem in broad principle, and Section 2 gives a lucid treatment of the precession and nutation, using vector and matrix notation, and deriving the major terms. At the end of each chapter there is a set of instructive examples for solution of varying difficulty, and some useful notes and references.

The study of orbital perturbations has given rise, in the past two centuries, to a vast edifice of mathematical developments and techniques (including the distinction of various classes of term in the expansion of the disturbing function, and the wide use of canonical transformations), and the author, in his wish to view the subject more directly from the point of view of the physical principles involved, betrays his impatience with some of these developments. This attitude is capable of leading to important new insights, and is not too much out of place in an introductory work; but it is a pity that the author expresses such especially violent lack of confidence in the Hamilton-Jacobi method (both in the Introduction and in the notes to Chapter 3), especially since he does not reach those problems where the method exhibits its power, as, for example, those related to the long-period features of orbital perturbations, or to the special conditions arising near small integer commensurabilities of period, or near the critical inclination in the artificial satellite problem.

P. J. MESSAGE

APPLIED MATHEMATICS

Mathematics in Physics and Engineering

By J. Irving and N. Mullineux. (Pure and Applied Physics: a Series of Monographs and Textbooks, Vol. 6). Pp. xvii + 883. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1959.) 11.50 dollars.

THIS book presents a comprehensive account of those parts of mathematics which find application in the solution of problems in physics and engineering. The tone of the book is practical and 'down to earth', with emphasis on solutions carried to the

numerical stage. It will be valued by the applied mathematician, at least as a reference book, because so much material is covered in its almost 900 pages of text. Each chapter is accompanied by a set of problems (with answers) and the text is copiously illustrated with problems worked out in detail. Thus the book is admirably suited to the needs of students, but it is not likely to help the research mathematician very much, since it is not a specialized text and the reference lists are not very extensive.

The first chapter deals with methods for solving partial differential equations, and includes a section on Cauchy's problem and the solution of hyperbolic, elliptic and parabolic equations. Chapter 2 is devoted to the solution of ordinary differential equations and it introduces a number of the special functions. On the other hand Bessel and Legendre functions receive amplified treatment in Chapter 3. Laplace and other transforms are introduced in Chapter 4, and some applications to problems of oscillation are discussed. Chapter 5 deals with matrix algebra, with emphasis on numerical work, such as solving equations or finding latent roots. Analytical methods in classical and wave mechanics are presented in Chapter 6, and these are illustrated by reference to the top and the linear harmonic oscillator.

Chapter 7 treats the calculus of variations. It covers the usual elementary problems and also isoperimetric problems and the Rayleigh-Ritz method. Some torsion and viscous-flow problems and some elastic plate problems are solved. There is a section on the binding energy of the helium-4 nucleus; but about twice the experimental value is obtained from a theoretical calculation, and then it is remarked that this shows that "the assumed interaction is not valid". It seems to me that it would have been better to omit this section, or, if the aim was to give an application of the variational calculus to theoretical physics, then an example where the result is more in accord with experiment might have been chosen.

Complex variable theory, the calculus of residues, and conformal transformations find widespread applications in physics and engineering; they are adequately covered in Chapters 8 and 9, which together occupy about 150 pages. General transform theory is dealt with in Chapter 10, and application is made to various problems of supersonic flow. Chapter 11 is on numerical methods, and Chapter 12 deals with integral equations, both analytical and numerical methods of solution being presented. The numerical treatment of integral equations deserves special mention. It goes further than that given in any other book known to me. There is an appendix of 80 pages on various topics in pure mathematics; it will mainly be of use for reference purposes.

The work should be of great assistance to senior undergraduates, and to physicists and engineers who move in the world of technology. If it is a matter of deciding, in a practical case, whether mathematics can help, this book will go a long way towards answering the question. So far as the actual printing is concerned, this is very clear. But the mathematical formulae and equations are frequently displayed in such a way that space is not utilized very efficiently, such as on p. 527 or 579. Formulae and prose might have been combined in some places, and in others the formulae printed on several consecutive lines might have all been put on one line. In spite of this, however, it must be admitted that the Academic Press has produced the book at a reasonable price.

L. S. GODDARD

Annual Review of Physiology

Vol. 22. Edited by Victor E. Hall, in association with Frederick A. Fuhrman and Arthur C. Giese. Pp. viii+725. (Palo Alto, Calif.: Annual Reviews, Inc., 1960.) 7 dollars.

THE "Annual Review of Physiology" has appeared regularly since 1939. The new number is much like its predecessors: it provides a fairly complete, but not very critical, summary of the year's literature. There is an interesting prefatory chapter by Dr. Franklin D. McLean, who has seen great changes in physiology since he took his degree in 1910—the year when Abraham Flexner's report on medical education appeared. He has come in close contact with many famous men—A. J. Carlson, L. J. Henderson, Otto Loewi, A. E. Cohn, Baird Hastings and many others, and has done much to make medicine scientific.

The new volume contains a cumulative index of chapter titles for Volumes 11–22. Articles on the adrenal cortex, heart, peripheral circulation, digestive system, kidney, reproduction, respiration, and three or four articles on the nervous system appear each year. This year there are articles on the comparative physiology of muscle and blood pigments and there are articles on nuclear function, genetics, the alimentary tract, vision, and the thyroid. There are no more reviews of Russian physiology.

The preface directs especial attention to the article on the regulation of volume of the blood by E. B. Reeve, T. H. Allen and J. E. Roberts of Colorado. In this article, quantities such as the rate of uptake of water from the gut, the rate of flow to and from the interstitial space, and the intracellular space are defined algebraically in terms of various symbols. The relations between these quantities are then expressed as formulae. The precise definitions given facilitate the discussion of the experimental papers reviewed, and will help to clarify thought in a complex field. This is a new departure for annual reviews; it is a constructive article and will provoke thought and criticism. It is hoped that more such reviews will appear in later volumes.

J. H. GADDUM

Ancient Mexico

An Introduction to the Pre-Hispanic Cultures. By Frederick A. Peterson. Pp. 313+24 plates. (London: George Allen and Unwin, Ltd., 1959.) 35s. net.

AN up-to-date account of Mexican archaeology is badly needed, and this book goes some way towards meeting that need. The author clearly knows his material, and he has had the advantage of long residence in Mexico, but these very qualifications may be responsible for his writing in some places in a way which will be understood better by the specialist than by the general public to which the book is directed. Rather a serious drawback is the way in which its general arrangement and tone obscure the differences between the Classic and Post-Classic Periods, particularly the introduction of large-scale war and violence with the arrival of the Toltecs at the beginning of the Post-Classic.

There are a number of points of detail which could be criticized; however, most of these will affect the general reader but little. Two only will be noted here because they will increase the natural difficulty which that reader may be expected to find in grasping the essentials of the Maya calendar and numerical system. One is a statement that "all the day names come 5 days later in the following year"; what is

meant is that the day name in the 260-day cycle of the first day of a 365-day year falls 5 days later in that list of names than that of the first day of the preceding 365-day year, so the result is that a given day name will be shifted backwards by 5 days, not forwards. The other is a misprint of 2259 against a Maya number 2258.

The publication of this book raised hopes that it might take the place of Vaillant's "Aztecs of Mexico", which is out-of-date in some respects, though still very valuable in others. Although it is quite a useful work, by comparison with Vaillant's it is a dull production.

G. H. S. BUSHNELL

Paper-Making Practice

By H. Hardman and E. J. Cole. Pp. xi+334. (Manchester: Manchester University Press, 1960.) 45s. net.

THOSE best qualified to write books on this subject seldom have the time or incentive to do so. This work was begun when the authors were lecturing at the Manchester College of Technology, and they have relied almost completely on the scientific literature and on machinery manufacturers' publications. It is therefore greatly to their credit that they have managed to assemble a remarkable amount of useful practical information, set out in simple language.

The book is a modified version of a series of articles which appeared in a trade journal, and it presupposes a fairly considerable knowledge of pulp and paper manufacture. Unfortunately, it is marred by some serious defects. Thus, the treatment of the subject is extremely un-even (wood pulping receives 74 pages, but rag and esparto pulping, of principal interest in Britain, are omitted); it is not particularly up to date (for example, in respect of methods of stock preparation, continuous pulping, fines removal, wire and felt construction); and of the approximately 110 literature references only two are subsequent to 1955. There are no index, no link-up between the body of the book and the bibliography, and no references to text-books (not even to "Clapper-ton"); and the text itself sorely needs editing.

Nevertheless, the book can profitably be read by the students and paper makers to whom it is addressed, and I hope that it will soon reach a second edition, when the above defects can be remedied and its value thereby greatly enhanced.

J. GRANT

Biographical Memoirs of the National Academy of Sciences of the United States of America

Vol. 34. Pp. vii+368+15 plates. (New York: Columbia University Press; London: Oxford University Press, 1960. Published for the National Academy of Sciences of the United States of America.) 40s. net.

WITH the exception of those of J. U. Nef (1915), L. V. Pirsson (1919) and L. B. Stillwell (1941) all the subjects of these memoirs died within the last decade, and most within the last three years. The memoirs are characterized by the high standard which has come to be associated with this series, and they will be valued also for the comprehensive bibliography which accompanies each memoir. Apart from those names already mentioned, those best known to British scientists are probably W. E. Bachman, R. A. Daly, C. F. Kettering, M. S. Kharasch, O. Meyerhof and W. R. Whitely.

PRODUCTIVITY OF THE SEA AND FRESH WATER

IT was appropriate that Section D (Zoology) of the British Association meeting at Cardiff should devote a session to the "Productivity of the Sea and Fresh Water" when the subject of feeding humanity loomed large in the deliberations of the Association as a whole. Indeed it was all the more timely for, as Dr. C. E. Lucas pointed out in the course of the session, one could see no mention at all of the sea or its potential in the programme of the Association's whole-day general symposium on "World Food and Population Problems".

The session was opened by Sir Alister Hardy, who outlined the natural economy of the sea by way of introduction and then, after stressing the need for getting more food from the sea, proceeded to discuss various ways in which the yield might possibly be increased. Apart from the development of new fisheries, better conservation of stocks already fished and other such fishery problems which would be dealt with by Dr. Lucas, he sought to answer the question: "Can we come any nearer to actually farming the seas?"

The manuring or the fertilizing of the waters with phosphates and other chemicals which had been so successful in confined freshwater fish culture could scarcely be used in the sea, he thought, except in certain very limited areas. The late Dr. F. Gross and his colleagues during the Second World War had demonstrated that such chemicals could be so used, but only in the land-locked arms of a sea loch; the open sea itself is too big a place to be treated in such a way on any large scale.

Sir Alister then referred to recent experiments conducted by Mr. J. E. Shelbourne, of the Fishery Laboratory at Lowestoft, in the rearing of young plaice in large nursery tanks until they were past the delicate stage at which the greatest mortality occurs in the sea. A number of sea-fish hatcheries, he said, have been established in the past, but it has been very doubtful if they really contributed much to the increase in the stocks of fish because the fry were liberated at far too early a stage; now, through Mr. Shelbourne finding how to keep them successfully until much later in their development, there is a new and real hope of adding materially to the fish stocks by such means.

He then recalled the experiments of the late Prof. Walter Garstang in the transplantation of young two-year-old plaice from the over-crowded coastal banks of Holland to the Dogger Bank, where they were shown to grow so much more quickly. Prof. Garstang had worked out the cost of transplanting millions of such young fish in ships specially fitted with tanks for the purpose, and had shown that such enterprise could yield a handsome profit to the industry; such farming, however, has not yet been possible because no one nation would put in the capital when all others would be free to reap the benefit. The time, however, will come, Sir Alister believes, when the need to get more food from the sea will bring about closer international co-operation in such matters.

Sir Alister ended his contribution by discussing another possible way of farming the sea which, while admitting that it lay very much in the future, he believed would be most important and should be prepared for. His ideas for such farming, he said, arose from considering the researches of Dr. Gunnar Thorson, the distinguished Danish marine biologist, who has shown that there is a much heavier competition on the sea-bed, from various animals such as starfish, for the food available for fish, than was originally thought. In a recent paper Dr. Thorson has demonstrated that such invertebrate predators will actually eat about four times as much food as will a quantity of fish of the same total weight; this, Thorson says, leads to "the amazing fact that only 1 to 2 per cent of the (potential) fish food is actually eaten by the fish".

These findings present a great challenge to marine biologists. Will future farmers of the sea be able to eradicate some of these pests and so step up the quantity of fish which may be carried on a given area? asked Sir Alister Hardy, and he went on to express his belief that this will eventually come about. If Dr. Thorson's calculations are correct, and if we could eliminate just a quarter of the pests and so allow the fish to have some 20, instead of just 2, per cent of the potential food supply, then we could make an area support ten times the quantity of fish that it does to-day. How could they be eliminated? Just as we harrow and roll the land in addition to reaping our crops, Sir Alister believes that we will in time systematically drag some combing or other devices over the sea floor at intervals to weed out the creatures that take the food from the much more valuable fish; and the pests themselves may well be converted into poultry food. Looking to the still more distant future, he believes that the fishermen of a hundred years hence may be frogmen working tractor-driven trawls sent down from parent ships above and pulling starfish eradicators over the sea bed. But whatever the future holds, he stressed, any such farming of the sea will require much more pure ecological research to determine just which of the animals we can do with in smaller numbers.

The second speaker was Dr. C. E. Lucas, director of Scottish Fisheries Research. The sea, he reminded us, is still our major highway, the very active natural boundary of all our lands, and an almost incalculable natural source of power. As the envelope of a sea-bed covering 70 per cent of the Earth's surface, it must be as rich in minerals as the land, or even richer. In addition, it is the source of our valuable marine fisheries.

With rare exceptions, the problem of the fishermen in taking their catch is a very difficult one; both they and the scientists have to work in the dark. Just before the Second World War, science began to help with the adaptation of the echo-sounder for 'seeing' fish as well as the sea bed, and since then scientists have used it with the under-water camera and television; but the fisherman still needs all the aid he can get. What are we doing about it? Dr. Lucas

asked. The answer, he said, depends on how we view the problem. On one hand, the knowledge we already have of the seas and their resources is a tribute to the skill of the fishermen and the scientific progress already made. From another aspect, with the vastness of the oceans and their potential value in view, both the harvest and the scientific effort are small.

Except during the Wars, over the past fifty years, Britain has taken each year about a million tons of fish from the north-east Atlantic: its present value at first sale is about £50 million. During that time the European catch increased steadily, and it stood at some eight million tons in 1957, when the Food and Agriculture Organization estimated the world's marine catch at nearly 30 million tons, compared with 20 million in 1938. These figures are themselves impressive enough until we compare them with those for agriculture: for the world, around 1,000 million tons of vegetable produce and probably 50-100 million tons of animal protein. So, despite its size, the sea's present yield is not so impressive after all, and it is chiefly this fact that has limited our research and exploratory investment. There is, however, another way of looking at this marine harvest; in terms of the yield per fisherman, it can compare very favourably at times with the agricultural yield per man. Why is it, then, that we get so little from the seas compared with the land?

There are, of course, many reasons, among which the problem of distributing the catch to populations far from the sea is important; it is being slowly conquered by research designed both to improve the means of preserving and transporting fish over greater periods and distances, and to provide forms of fish-meal which shall be attractive for direct human consumption. Primarily, however, it is because we are still very old-fashioned and unscientific in our exploitation of the seas. This is neither a criticism of research work nor of the hard-working fishermen. The fisheries scientists must necessarily direct a large proportion of their effort to the problems of the industry as it exists, while the fishermen can only afford to fish for profitable markets. It is simply a statement of fact, for there are many more fish, and other animals, in the sea than ever came out.

The conventional fish stocks are based on the continental shelf. The fish fluctuate in abundance, largely in response to variations in the ocean currents and the plankton which 'supports' them and the animals of the sea-bed. But their abundance also depends on man himself, with his frequently wasteful fishing; success has usually led to ruthless exploitation until the stock has been unable to recruit and grow as fast as man has reaped. In slowly reproducing animals such as whales, this has led to near extinction; but fortunately most fish stocks are more resilient and respond rapidly to a reduction in fishing.

These matters are among the objects of study in marine laboratories and particularly fisheries laboratories. Here Dr. Lucas went on to review some of the important lines of fisheries research carried out at these laboratories; but as he said, viewed in relation to agricultural and industrial research, the whole is pathetically small. Yet it has given a general picture of the sea and its riches which demands further investigation and exploitation.

The seas occupy more than 70 per cent of the world's surface and have their own natural crop of plants and animals. While these vary considerably

from place to place, we now know that their overall productivity, in terms of plant matter, is at least as great as that of the land, about 100,000 million tons (+) per annum. One of our problems at present is to know just how productive it is, and the final answer may be that, acre for acre, it beats the land. Here, however, comes one of the big differences. On the land, most of the basic production is in terms of grass, trees and other plants which are often directly usable. With the exception of the seaweeds, on which a not unimportant industry is now developing, production in the sea is based on countless myriads of unicellular plants, from which vast crops might be taken, except that they are individually so small that we do not know how to harvest them. At present we have to rely on the fish and whales to harvest them for us, mainly via the small animals which feed directly on the plants, and with them form the plankton. Only in a few instances do we know much of the food-chains in the sea; but we do know that there is a great loss in productive efficiency at each stage, that is, between the plants and the animals that feed on them, between these animals and the next larger ones, etc.—perhaps 80-90 per cent in each step. So that the original 100,000 million tons (+) of plant matter produced is probably reduced to about 1-2,000 million tons (+) in terms of animals of a size conventionally acceptable for food. Yet that is far greater than the 30 million tons caught at present. Not all these sizeable animals are fish, of course, but a large fraction of them are; of the others, many are molluscs or crustaceans such as have long been familiar to us as food, and many more are representatives of animal groups which already provide food in one part of the world or another.

Considered from this position, can we—either Britain or the world as a whole—afford to view the seas merely as a source of 30 or even 50 million tons of fish? Even in food terms alone, it is a potential source of protein too valuable to be taken in the present somewhat primitive way. But the oceans have other significance for us. Can we afford any longer to treat marine research as almost the Cinderella of the sciences? Does it not deserve a place among the major groups of investigation basic and applied? asked Dr. Lucas. He then discussed in more detail the further potential food supplies we can anticipate from the sea. He dealt with increases to be expected, on one hand through a better and international conversion of stocks already fished, and on the other through the exploitation of new stocks as yet untapped. He also considered new fisheries for smaller species of fish, at least for conversion to fish-meal, if not for direct human food; and this could free for man's consumption fish such as the herring which are being unnecessarily taxed for such uneconomic purposes as animal feeding. Then, after considering further some of the possible farming methods discussed by Sir Alister Hardy, he turned to the possible harvesting of plankton.

There are, Dr. Lucas said, the distant but enormous possibilities of the natural plankton itself. Even now the larger zooplankton is caught and eaten in some parts of the world where circumstances are particularly favourable. In general, however, we have not yet the means to harvest either the phytoplankton or the zooplankton; but, in the richer areas, such as the polar regions, the annual production presents a challenge which may some day be accepted. At present we can merely set against the difficulties and

the costs, and the fact that whales and fish harvest these for us freely, the loss we incur by taking less than 0.1 per cent of the total marine production. To acquire that fraction the world uses more than a million vessels of various sizes and probably more than 4,000,000 men. Some day, when the incentive is great enough, as for many 'miracles' it was during the War, some of us will see that in true perspective, and decide that such an effort deserves a greater return and therefore a major effort to see whether a solution cannot be found.

The sea, then, at present gives us some 30 million tons of animal protein, etc., and we can have every confidence in that being at least doubled by the simple application of present knowledge and techniques, and probably more cheaply in human effort than now.

Finally, Dr. Lucas said that in Britain, we are now spending about £1½ million a year on marine research of all kinds, compared with about £7 million on agricultural research, to say nothing of medicine, defence and atomic energy. We are also talking of spending millions more on space research, and the Americans and Russians are thinking in terms of hundreds of millions a year. Yet there are vast unexplored spaces off our coasts which are intellectually and physically as exciting as any; we know less of the sea-bed than we do of the face of the Moon.

The two contributions on freshwater fisheries to the symposium which followed were concerned with tropical conditions and were more specialized. Dr. R. S. A. Beauchamp, until recently director of the Jinja Laboratory on Lake Victoria, dealt with the lake fisheries of East Africa. The abundant light and heat of the tropics, he said, provide ample energy, so that, other things being equal, tropical lakes should be more fertile and more productive than those in temperate regions. The abundance of fish and other animals (hippopotami, crocodiles, etc.) found when some of the East African lakes were first visited had seemed to provide proof of this, yet their exploitation has shown that they are not as productive as they seemed to be; research has given at least a partial explanation.

For a number of years the stocks provided all the fish required. With the increase in the human population, however, the demand for fish increased and the fishery was greatly developed; in consequence, in Lake Victoria the fish were reduced to about one fiftieth of what they were. This has not caused the alarm it should, because the gross annual yield has been maintained by increasing the fishing effort. The methods for investigating the productivity of these lakes are the same as those used for temperate ones; but only after a time does one realize how very different a tropical lake is. In a temperate-zone lake, the vital processes go on at a rate determined by the weather and the changing seasons; in the tropics these are constant or vary only slightly. Thus, he said, puts the question of what determines the rate of productivity in rather a new light, and it becomes apparent that in a tropical lake this is determined by its own characteristics; there are certain physical circumstances which limit production in any given lake, but within such limits it is determined by the biological processes themselves.

With this idea in mind, one is forced to consider what these lakes were like before they were heavily exploited: when they contained, according to the

earliest records, very many more fish than they do now. These records have by some been discredited or considered as exaggerated. However, there are, in East and Central Africa, still a few lakes that have not been heavily exploited or have only been opened up recently, and all these provide evidence for the validity of the records regarding the number of fish originally found in lakes such as Lake Victoria.

It is generally recognized that any natural complex of plants and animals, if left to itself, will develop so as to produce and support the maximum number of living organisms. It is also fairly apparent that, almost without exception, man's interference in any such natural biological resource leads to its deterioration. The African lakes vividly illustrate these two contentions. Man has caused so much damage because he strikes at the most crucial link in the succession—where plant material is being converted into animal material. This conversion is brought about, not, as in other lakes, by the invertebrate animals, but directly by fish belonging to the genus *Tilapia*, which feed on phytoplankton.

With an excess of light and heat, a limit to plant growth is set by the rate at which nutrients become available. In Lake Victoria (and probably some other lakes) a primary deficiency has been shown to be a shortage of sulphate; and it was also found that the inflows contained little or none of this. However, the main supply of nutrients in a large lake is not from its inflows but from its bottom deposits. In Lake Victoria the organic content of the bottom muds was found to be extremely high, containing enormous quantities of organically combined sulphur. Here in contact with the water we have an abundance of the very substance that constitutes a deficiency. How this comes about is not yet fully explained, but the mud contains organisms which seem to prevent the usual processes of decomposition and decay; thus the nutrients in the plankton that falls to the bottom are largely removed from circulation. For this reason, it is very desirable that as much as possible of the plankton should be eaten in order to keep up the general level of fertility by the return of animal excretion; to this end considerable stocks of *Tilapia* should be maintained in the Lake. Unfortunately, these fishes form the basis of the commercial fisheries and suffer the severest exploitation. Twenty-five years ago an officer of the Sleeping Sickness Department who had spent most of his life on Lake Victoria said he thought it was becoming a watery desert; this is even more true to-day.

The concluding speaker was Dr. C. F. Hickling, fishery adviser to the Colonial Office, who described experiments on the effects of fertilizers on the fish yield at the new Fish Culture Research Station in Malacca. It is well known, he said, that the natural production of fish in a pond can be greatly increased by the use of fertilizers and the supply of supplementary foods. But fertilizers are cheap, both in cost and labour, whereas foods are by comparison expensive and tending to be more so. Therefore fish-pond economy demands that the maximum increase in fish production should be got by the use of fertilizers, with supplementary feeding as an extra.

Temperatures at Malacca are high and show little variation (27° C. at night; 32° C. by day), so growth is very rapid. Since earlier work suggested that a neutral or slightly alkaline reaction is essential for the successful use of fertilizers, the first series of trials tested the effects of graduated doses of calcium

carbonate, given as powdered limestone, on the water and the fish stocked in the ponds. All the experiments were done in 36 one-acre ponds arranged as a Latin square (6×6) and each stocked with 250 common carp and 200 *Tilapia mossambica*; after six months the ponds were drained and the fish crop weighed. It was shown that the yield of fish was not increased even though acidity was neutralized and alkalinity increased four-fold.

Next the same ponds were used to test the effect of 20 lb. of phosphate (P_2O_5), given as triple super-phosphate, on the fish production at three different levels of limestone dosage, and also the effect of potash (K_2O) with and without phosphate, against an untreated control. The potash without phosphate gave no significant increase in yield over that of the control or of the former experiment; the phosphate, however, gave an important effect in every case: even in the unlimed ponds, it increased the fish crop

from 93 to 217 lb., and in the limestone ponds it was increased to 344 lb. In a third series of experiments it was shown that the addition of nitrogen (as calcium nitrate) gave no significant increase over phosphate alone, and it also showed that the addition of 20 lb. of phosphate gave as good a crop of fish as nearly 7 tons of cowdung. 40 lb. of phosphate gave the highest yield of all—an average of 373 lb. with a maximum of 551 lb. In summing up, Dr. Hickling said the lessons to be learnt from these experiments are, first the paramount importance of phosphates, and secondly the rapid rate of turnover, which is to a large extent a function of temperature; this latter factor, he believes, accounts for the far better utilization of phosphates shown at Malacca as compared with earlier German experiments in colder temperate waters.

Both the marine and freshwater contributions gave rise to a good general discussion.

SCATTERING OF HIGH-ENERGY ELECTRONS BY PROTONS

By PROF. R. R. WILSON, DR. K. BERKELMAN, PROF. J. M. CASSELS*, F.R.S.,
and DR. D. N. OLSON

Laboratory of Nuclear Studies, Cornell University, Ithaca, N.Y.

THE elastic scattering of electrons by protons is described¹ by the Rosenbluth formula (lengths will be expressed in fermis, and $\hbar = c = 1$. For momenta $1 f^{-1} = 197 \text{ MeV./c.}$):

$$\frac{d\sigma}{d\Omega} = \frac{\alpha^2}{4E^2} \frac{\cos^2\theta/2}{\sin^4\theta/2} \left[1 + \left(\frac{2E}{M} \right) \sin^2\theta/2 \right]^{-1} \left\{ F_1^2 + \frac{q^2}{4M^2} \left[2(F_1 + \kappa F_2)^2 \tan^2 \frac{\theta}{2} + \kappa^2 F_2^2 \right] \right\} \quad (1)$$

where $\frac{d\sigma}{d\Omega}$ is the laboratory differential cross-section,

α is the fine structure constant, E is the laboratory energy of the incident electron, θ is the laboratory angle of scattering, M is the proton mass, $q^2 = 4E^2 \sin^2\theta/2 [1 + (2E/M)\sin^2\theta/2]^{-1}$ is the square of the four-momentum transfer, and $\kappa = 1.79$ is the anomalous magnetic moment of the proton in nuclear magnetons. The form factors F_1 and F_2 are associated respectively with the Dirac and Pauli interactions of the proton with an electromagnetic field.

The formula, of course, relies on the validity of conventional quantum electrodynamics, and also on the absence of fourth-order processes in which two photons are exchanged between the electron and the physical nucleon. Both assumptions are expected to be valid in the conditions of the experiment described here, although the second one may well break down at energies not much greater².

For convenience a cross-section $\frac{d\sigma'}{d\Omega}$, loosely referred

to as the 'point proton cross-section', may be defined by writing $F_1 = F_2 = 1$ in the formula; then experimental results can be expressed in terms of $F^2(q^2, \theta)$, where:

$$\frac{d\sigma}{d\Omega} = F^2(q^2, \theta) \frac{d\sigma'}{d\Omega} \quad (2)$$

Clearly F can be expressed in terms of F_1 and F_2 as required.

Hofstadter *et al.*³, using electrons with energies up to 650 MeV. from the Stanford linac, have studied the scattering at 75° ($q^2 \lesssim 11 f^{-2}$) and 135° ($q^2 \lesssim 17 f^{-2}$). Their results are well fitted by writing:

$$F = F_1 = F_2 = (1 + 0.0533 q^2)^{-2} \quad (3)$$

A recent letter by Hand⁴, who also used the Stanford linac, reports measurements at 135° for $q^2 \approx 26 f^{-2}$. These results are also consistent with equation (3).

This article reports an investigation of the scattering in which q^2 ranged up to $25 f^{-2}$ at 66° and at 112° . As will be seen, the results at the higher angle agree with Hand's. At the lower angle, on the other hand, a variation of F^2 with θ is revealed which can only mean that F_1 and F_2 are not equal.

Apparatus and Procedure

Figs. 1 and 2 show vertical and horizontal views of the general layout and of the counter telescope. The electron beam of the Cornell synchrotron spiralled inwards at the peak of the magnetic cycle,

* Now at the Chadwick Laboratory, University of Liverpool.

Fig. 1. Plan view of the apparatus described in the text

as a result of controlled decrease of the radiofrequency accelerating voltage. For periods of about 1 msec., repeated 30 times per sec., the electrons bombarded polyethylene or carbon targets in a scattering chamber located in one of the straight sections. The targets were in the form of rods about 1/16 in. square, disposed horizontally in the median plane of the synchrotron at an angle of 45° to the beam direction. The tips of the targets were 1.1 cm. inside the normal equilibrium orbit of the beam. Discoloration of the polyethylene showed that the targets were bombarded at distances up to 1/16 in. back from the tips.

A totally absorbing ion chamber, or quantameter⁵, integrated absolutely the bremsstrahlung emitted from the target. Knowledge of the radiation-length of the target materials at the various electron energies gives directly the effective product of the target thickness and the incident electron charge, which is the quantity required for cross-section calculations. It was evident that on the average the electrons traversed the target about ten times before being finally lost from the synchrotron.

Photographs were taken of the bremsstrahlung spot immediately in front of the ion chamber. Usually these showed a clean spot about 1/4 in. in diameter, which checked that electrons were not hitting objects, other than the targets, in or near the scattering chamber. In the early stages of the experiment a second diffuse spot was sometimes caused by electrons hitting a beam-detecting device at the upstream entrance to the chamber; this improper mode of operation was associated with incorrect monitoring and low measured cross-sections. The trouble was eliminated by adjustment of the in-phase correction coils which steer the synchrotron beam at high energies.

Scattered electrons, or recoil protons, left the scattering chamber through a 0.005-in. 'Mylar' window and were then deflected magnetic-

ally by a single quadrupole lens. This produced vertical focusing of the particles passing over or under a central obstacle 3.7 in. high, made of lead and copper. The momentum window of the spectrometer was defined by this obstacle and by the plastic scintillator A, the maximum height of which was 1/8 in. In vertical section this scintillator had the shape of a truncated diamond, in order to obtain the best possible bias curve for the pulses.

The quadrupole lens was, of course, defocusing horizontally, and therefore scintillator A was made 8 in. wide. In a typical run the collected particles were emitted at semi-horizontal angles up to 0.97° , measured at the target with respect to the central ray; the total solid angle collected by the spectrometer was 4.41 milliradians.

The momenta of the particles varied with the horizontal angle of emission, an effect which was only appreciable for recoil protons. To compensate for it, scintillator A was turned through a small angle (for example, 18° at 1,205 MeV.) round its vertical axis, counterclockwise as seen from above.

For a point target on the axis the theoretical curve of detection efficiency versus magnetic field gradient, for a fixed momentum particle, was trapezoidal in shape. It had an almost flat top and a typical full width of 3.1 per cent at half-efficiency. In practice the resolution curve was smeared by the finite height of the target and various multiple scattering processes, especially for recoil protons. However, the area under the peak should not be seriously changed by these effects, and so the cross-sections were computed by integrating peaks in the experimental counting-rate as a function of magnetic field gradient. Actually the voltage across a shunt in series with the exciting coils of the magnet was used as the independent variable, and the areas multiplied by an appropriate constant. At the highest momenta the field gradients were not quite proportional to the existing currents,

Fig. 2. Side view of the target, spectrometer, and counter telescopes. The inset shows an enlarged view of the two scintillation counters

Fig. 3. The counting-rate as a function of magnet current; protons recoiling at 66° from collisions of 781-MeV. incident electrons

Fig. 4. The counting-rate as a function of magnet current; electrons scattered at 66° from collisions of 781-MeV. incident electrons

and a differential correction (≥ 9 per cent) was made for this.

The procedure just outlined was used for (a) the 66° scattering of 587, 684, 781, 879 and 1,034 MeV. electrons, (b) the 112° scattering of 320 and 761 MeV. electrons, and (c) the protons recoiling at 66° from the scattering of electrons with energies of 684, 781, 982, 1,034, 1,173 and 1,205 MeV.

The counting rate was measured only in the region of the peak for (d) the 66° scattering of 982, 1,085, 1,173, and 1,215 MeV. electrons, and (e) the 112° scattering of 909 MeV. electrons. The corresponding

cross-sections were evaluated using the line shape established in the full sets of measurements.

The other two counters in the telescope were used to reduce backgrounds. Counter *C* was inoperative when the comparatively slow recoil protons were being detected, and the bias on the plastic scintillator counter *B* was raised so that relativistic particles were not detected. Coincidences between counters *A* and *B* were required, the effective pulse widths being about $0.5 \mu\text{sec}$.

When electrons were being detected the bias on counter *B* was lowered, and counter *C* was brought into operation. This was a lead glass total absorption Čerenkov detector, which produced recognizably large pulses when the desired electrons arrived. Triple coincidences between counters *A*, *B* and *C* were required, the effective width of the mixed pulses being about 20 ns. for *A*, 200 ns. for *C*, and $0.7 \mu\text{s}$. for *B*. Each triple coincidence event opened an electronic gate, allowing the output from counter *C* to reach a pulse-height analyser.

At all times the electronic equipment was gated by a 4 ms. pulse locked to the peak of the magnetic cycle of the synchrotron. This reduced corrections for cosmic ray events (≤ 10 per cent, but usually negligible).

Results

Figs. 3 and 4 show respectively the recoil proton and the scattered electron peaks observed at 66° from 781-MeV. incident electrons. The ordinates are the coincidence counts observed per 'sweep' of the quantimeter (1 sweep = 4.97×10^{14} MeV.), and the abscissae are the voltages in the spectrometer shunt.

The counting-rate as a function of the magnet current after subtraction of the rate from carbon

Fig. 5. Line shape of the peaks caused by elastically scattered electrons

Fig. 6. Experimental results, including Stanford results at high q^2 . The full line is given by the formula $F^2 = (1 + 0.0533 q^2)^{-1}$, while the dashed line is fitted to the 66° experimental points at high q^2 .

Fig. 7. The individual form factors required to reproduce the full line of Fig. 6 at 135°, and the dashed line of Fig. 6 at 66°.

The carbon target results have been multiplied by a normalizing factor $\beta = 0.89$, which equalizes the effects of the carbon nuclei in the two target materials. Rather clean elastic peaks are revealed in both figures, although there is a small inelastic tail in the proton distribution. Fig. 5 shows the line shapes observed in all the complete sets of electron measurements, before correction for saturation.

It was found that the height of a peak decreased slowly if a given polyethylene target was bombarded for a long time. Presumably this was due to ejection of the hydrogen from the target, an effect probably correlated with a brownish discoloration which also appeared. The polyethylene targets were changed every few hours and a suitable correction for ageing was established and applied (≤ 3 per cent).

Finally, the usual radiation correction (≤ 13 per cent) was applied to allow for the emission of bremsstrahlung in the electron-proton scattering process.

The results, expressed as a plot of F^2 against q^2 , are shown in Fig. 6. For comparison some of the results of Hofstadter *et al.* are also shown, together with those of Hand.

Discussion

The results of the present experiment clearly agree well with the Stanford data wherever they overlap, that is for $q^2 \lesssim 11 \text{ f}^{-2}$ when $\theta < 90^\circ$, and for $q^2 \lesssim 26 \text{ f}^{-2}$ when $\theta > 90^\circ$. Often the form factors at low q^2 are expanded in the static approximation:

$$F_{1,2} = 1 - \frac{1}{6} a_{1,2}^2 q^2 + \dots \quad (4)$$

where $a_{1,2}$ are the root mean square radii of the charge and the anomalous magnetic moment of the proton. Thus no change is indicated in the conclusion of Hofstadter *et al.* that these radii are about 0.8 f . It should be noted, however, that equation (4) is subject to relativistic and dynamic corrections of the order of q^2/M^2 , so that the exact physical significance of this line of interpretation is not very clear.

At high values of q^2 the points for $\theta < 90^\circ$ (circles and dashed line in Fig. 6) flatten out⁶ and lie consistently higher than the points for $\theta > 90^\circ$ (squares and full line in Fig. 6). This behaviour indicates that F_1 and F_2 are not equal, and in fact an average of the points near $q^2 = 20$ gives $\frac{F_2}{F_1} = 0.37 + 0.17 - 0.14$. Fig. 7 shows the individual values of F_1 and F_2 , which would give the dashed and full lines of Fig. 6 at angles of 66° and 135° respectively. The two form factors must behave in this general fashion, although at present their values have clearly not been determined with precision. (This conclusion was reported by one of us (R. R. W.) to the Tenth Annual Rochester Conference on High Energy Physics (August 25–September 1, 1960). A subsequent paper by Prof. R. Hofstadter included a similar deduction on the basis of recent work at Stanford.)

The flattening out of F_1 at $q^2 \approx 12 \text{ f}^{-2}$ must be associated with the inner structure of the proton, at radii of the order of 0.3 f . The charge density in this region may be expected to include contributions from virtual states containing nucleon-antinucleon pairs, kaons and multiple pions. It is likely to be some time before these various effects are disentangled with any certainty.

The most promising line of theoretical attack is based on the dispersion theory^{7,8} of the isotopic scalar and vector parts of the nucleon form factors. Unfortunately there are no general theorems relating the neutron and proton form factors, so that data on electron-neutron scattering at high q^2 , for both large and small angles, are needed before further progress can be made.

We are indebted to Dr. P. C. Stein and Mr. D. Edwards for help in taking readings, and to Mr. A. Contogouris for helpful discussions on theoretical matters. Mr. P. D. O'Neill gave valuable help with numerical computations. The co-operation of the synchrotron crew is gratefully acknowledged.

SOME MOLECULAR DETAILS OF THE SECONDARY STRUCTURE OF RIBONUCLEIC ACID

By PROF. JACQUES R. FRESCO*, BRUCE M. ALBERTS
and PROF. PAUL DOTY

Department of Chemistry, Harvard University, Cambridge, Mass.

THE Watson-Crick structure for deoxyribonucleic acid¹ and the Pauling-Corey structure for the α -helix in proteins² represent unique chain conformations that permit maximum hydrogen bonding and impose rigidity on the otherwise flexible chains. The several highly specific functions of ribonucleic acid suggest that it also must have a unique spatial arrangement that only a periodic chain conformation, that is, a secondary structure, can provide.

Nearly two years ago, it was shown that a number of physical chemical observations on ribonucleic acid were consistent with its having a partial (40–60 per cent) helical structure in dilute neutral saline at low temperature^{3,4}, and these conclusions have since received further support^{5–8}. At that time it was proposed that each chain consists of a number of imperfect hairpin-like helices similar in character to those of deoxyribonucleic acid, united by flexible, unstructured regions. However, the proposal lacked definition on two important points: it was not clear how half the bases in ribonucleic acid could fit into helical regions; and in connexion with this, it was not known how large a helical region had to be in order to satisfy the observed thermal stability. The object of this communication is to show how recent experimental studies on synthetic polynucleotide analogues remove these difficulties and permit a more specific delineation of the secondary structure of ribonucleic acid.

Nature of the Base Pairs: It is now possible to propose with some confidence that the helical regions of ribonucleic acid are similar to those in deoxyribonucleic acid, that is, they contain the adenine-uracil and guanine-cytosine hydrogen-bonded base pairs. Of the many base pairs which have been examined in helical polynucleotide structures, these have been found to interact most strongly^{9,10}. Furthermore, they appear to be the only pairs which are mutually conformable in a regular helical framework. Consequently, the structure common to the adenine-uracil and guanine-cytosine pairs can be expected to be favoured, and since in this framework all other base pairs are either sterically intolerable or are separated by too large a distance to form hydrogen bonds, their existence is regarded as unlikely. Consistent with this view, a linear correlation has now been demonstrated between the thermal stability of a variety of ribonucleic acids and their guanine-cytosine contents (Fresco, J. R., and Givelber, H., unpublished observations).

Accommodation of Successive Base Pairs: The consequence of adopting a deoxyribonucleic acid-like structure for the helical regions of ribonucleic acid is that severe sequence requirements would appear to

be necessary in order to realize the 40–60 per cent level observed in ribosomal^{3,4}, tobacco mosaic virus^{3,4}, and transfer ribonucleic acid¹¹. For example, a random sequence of the four bases can readily be shown to allow only about 20 per cent helical development even if two adjacent base pairs are accepted as 'helical regions' (see Fig. 1a). However, when it was found that a synthetic copolymer containing a random arrangement of adenylic, guanylic, cytidylic and uridylic nucleotides displays about the same helical content as ribonucleic acid^{3,4}, the notion that sequence restrictions make possible the high helical content had to be rejected.

An attractive solution to this dilemma has come from a recent study of helix formation between homopolymers and copolymers of adenylic and uridylic acids which revealed an additional degree of freedom in polynucleotide conformations¹². In this work it became evident that when chains of poly-uridylic acid were mixed with chains of a copolymer of adenylic acid and uridylic acids (with adenylic acid the dominant component), the optimal base-pairing occurred when the number of uridylic acid residues in poly-uridylic acid equalled the number of adenylic acid residues in the poly-adenylic-uridylic acid chain. From this it was concluded that all the uridylic acid residues in the copolymer were looping out from the helical structure, so that only adenylic acid residues remained opposite the uridylic acid residues of the poly-uridylic acid chain. Comparable results were obtained when the interacting species were poly-uridylic-adenylic acid and poly-adenylic acid. The helix-with-loops thus formed is weaker than the equivalent helix without loops, because the presence of

For a particular random sequence polynucleotide of 22 residues the maximum helical region has 3 paired bases. The average is 2

When loops are permitted, the maximum helical region has 7 paired bases. The average is 6

Fig. 1. Effect of loop formation on the efficiency of base-pair interaction

* Established Investigator of the American Heart Association, Present address: Department of Chemistry, Princeton University, Princeton, New Jersey.

loops brings about a concentration of negative charges and therefore increases electrostatic repulsive forces, and because the accommodation of the loops probably introduces some strain in the adjacent helical regions. Consequently, loops conspire with the shortness of the helical regions to lower the T_m value (where T_m is the temperature at the mid-point of the helix-coil transition) which is a measure of helix stability. In the case of poly-uridylic-adenylic acid and poly-uridylic acid, helical complexes were stable at 25° C. only if they contained less than about one-third of their residues in looped form. In these complexes all the loops occur only in the poly-uridylic-adenylic acid chain.

In ribonucleic acid the helical regions are shorter and the loops probably exist in both strands of these regions. These factors would tend to lower the fraction of residues that could be permitted in a helical region. However, the presence of the much stronger guanine-cytosine bonds¹⁰ would probably more than compensate for this effect. For example, a helix having equal numbers of adenine-uracil pairs ($T_m = 61^\circ$) (refs. 3, 4) and guanine-cytosine pairs ($T_m = 110^\circ$) (ref. 10) bonds would have a T_m 20–25 deg. higher than an equivalent helix with only adenine-uracil bonds. Since ribonucleic acid can be expected to have many helical regions with at least this degree of content of guanine-cytosine bonds, it appears safe to conclude that these regions will be stable at 25° C. even if they contain as much as one-third of their residues looped outside the helix. Thus, loops permit a greatly increased incorporation of adenine-uracil and guanine-cytosine pairs into helical regions.

The Minimum Helix Size: Before exploiting the degree of freedom that loops provide in ribonucleic acid, one other restraint must be noted. Even without loops, the T_m of a given helical structure will decrease with decreasing length and will at some value pass below some temperature of interest, say 25° C. Current experiments (Fresco, J. R., Blake, R., and Doty, P., unpublished observations; also ref. 13) in which T_m has been determined for various helical complexes of long-chain poly-uridylic acid, and uniform oligonucleotides of adenylic acid show that T_m becomes equal to about 25° for the tetraadenylic acid. Again, this may be lowered still more if the long-chain poly-uridylic acid is replaced by a short oligo-uridylic acid. But, as before, the existence of guanine-cytosine bonds in ribonucleic acid will probably more than compensate for such weakening effects. Hence, we can estimate that the minimum size of helical regions stable at 25° C is about four nucleotide pairs, and that six nucleotide pairs, for example, would probably accommodate at least three looped-out residues at 25°. This, then, defines helical regions of minimum stability. Since the major part of the melting curve for all samples of ribonucleic acid occurs between 20° and 90°, it would be expected that the majority of helical regions in ribonucleic acid are longer or have a smaller percentage of loops.

Summary of the Features involved in the Secondary Structure of Ribonucleic Acid: The three points discussed above can be combined with the relevant observations of the earlier work to provide a summary of the behavioural characteristics of ribonucleic acid which should govern the elaboration of its secondary structure. The experimental support for these points is now fairly substantial, although further work can be expected to lead to minor revisions.

(1) Ribonucleic acid is a single-stranded molecule^{14–17} the secondary structure of which arises from intramolecular interactions.

(2) The most stable of several possible secondary structures is the two-stranded helix of the deoxy-ribonucleic acid type in which adenine-uracil and guanine-cytosine pairs are hydrogen-bonded. The guanine-cytosine pair, being stronger, is preferred.

(3) At 25° and moderate ionic strength, the minimum length of helix without loops is about four nucleotide pairs.

(4) Under the above conditions, if the helical region contains an approximately equal quantity of adenine-uracil and guanine-cytosine bonds, six nucleotide pairs can accommodate at least three looped residues (one fifth of the total involved). Longer regions can have up to one-third of their residues looped out from the helical structure without destroying their stability.

(5) Ribonucleic acid takes up its most stable conformation as a result of a lateral mobility which permits exploration of most competitive conformations^{18,19}. The chain adjustment made possible by the looping of residues in helical regions is a vital part of this process.

(6) The most stable helical regions arise from interactions between adjacent sections of the polynucleotide backbone. Entropy considerations suggest that interactions between distant sections are unlikely, since they would lead to very highly restrictive conformations. Thus, the helical regions take the form of hairpin turns which require a minimum of three unbonded nucleotides to connect the antiparallel hydrogen-bonded chain sections. The spatial parameters of the helix are probably close to those determined for poly-(adenylic + uridylic acids)²⁰.

Illustrations of Secondary Structure: Our proposal is that this set of conditions is sufficient to indicate the essential nature of the deployment of nucleotides in the characteristic conformation of ribonucleic acid. The kind of structure that develops from these conditions can be illustrated in two ways. In one, we can take a short sequence of nucleotides chosen at random from an equimolar mixture and work out all conformations compatible with the above conditions. In another we can take a much longer sequence and show typical conformations which satisfy these conditions but may not represent the optimal conformation.

The first approach is summarized in Fig. 1. Here a particular random sequence of 22 nucleotides has been examined. Without the possibility of loops, the longest helical region has only three adjacent base pairs and is therefore below the stability condition specified. When loops are permitted, however, 7 adjacent base pairs can be formed, resulting in 63 per cent of the bases being in the helical region. Indeed, the average of all conformations is 6 pairs, or 54 per cent, of the nucleotides in helical regions, all above the minimum size permitted.

In the second example, we have taken a random sequence of 90 nucleotides, thus using a size comparable with that occurring in transfer ribonucleic acid. If one attempts to obtain maximum length of the helix, results such as that in Fig. 2 are obtained. Here 60 per cent of the bases are paired, but in the central section the concentration of loops is so high that this section would not remain helical according to the above conditions. Consequently, only about 40 per cent of the bases could be paired. Alternatively, one can explore many other conformations and these lead

ribonucleic acid. In the particular case of transfer ribonucleic acid, the specificity of amino-acid uptake may be due in part to the stabilized topology of a portion of the ribonucleic acid molecule in the vicinity of the acceptor end. This model provides adequate possibilities in this direction.

In ribosomes, ribonucleic acid must maintain stable connexions with the protein component so that a swollen matrix is preserved. While little appears to be known about the details of this organization, two recent observations suggest that our model is relevant to ribonucleic acid within the ribosomes. One is that the hydrogen-bond content of ribonucleic acid within the microsomes is similar to that estimated for the isolated ribonucleic acid^{17,22}. The other is that the X-ray diffraction pattern of ribosomes bears a close similarity to that of the isolated ribonucleic acid, once the protein diffraction is subtracted²². Consequently, we can visualize that the unpaired bases in the loops or in open-chain regions provide potential sites for structural connexions with amino-acid residues of the ribosomal protein. Of course, the more significant role of ribonucleic acid in the ribosome would appear to be that of recognition of an incoming transfer ribonucleic acid-amino acid molecule, its momentary deposition at a particular locus, and its later ejection. The stability of many of the helical regions in ribosomal ribonucleic acid at cell temperature is marginal, and thermal fluctuations might well lead to the momentary opening of a significant proportion of the regions envisaged in our proposal. In that event the complementary region of the transfer ribonucleic acid molecule could readily be accepted by base-pair interactions, resulting in a short helical region. Subsequent disruption of this helical region at the time of a later thermal fluctuation, perhaps resulting from the formation of peptide bonds, might provide a means of return to the former state with the liberation of the temporarily bound ribonucleic acid molecule. Such possibilities are clearly inherent in the helical structure described here.

In concluding, we would like to emphasize that the secondary structure of ribonucleic acid that we have detailed is dictated to each molecule by its own nucleotide sequence; and that the unpaired bases in these molecules constitute a tertiary structure, in that they are in most cases held in fixed relation to each other either on the same helical region or on different ones. This provides for new possibilities in coding and information transfer that are not inherent in a structureless single strand or in a perfect base-paired helix.

REPORT OF THE TELEVISION ADVISORY COMMITTEE, 1960

THE Television Advisory Committee, set up in October 1952 under the chairmanship of Admiral Sir Charles Daniel, had as terms of reference: "To advise the Postmaster General on the development of television and sound broadcasting at frequencies above 30 megacycles per second and related matters, including competitive television services and television for public showing in cinemas and elsewhere". The Committee has now issued its third report* (the earlier reports were issued in 1953 and 1954 respectively) and is concerned entirely with possible ways of allocating wave-bands to alternative programmes, and with possible new scanning-line standards to link up Britain with the rest of Europe. Colour television also is briefly referred to, but nothing new is said, though a later report on this specific subject will be issued by the Committee "as soon as they are in a position to do so".

The questions discussed in the present report are wholly technical, but even within this limited sphere

it is a rather disappointing document. The various technical questions cannot fully be answered, as this Committee of course realized, without relating them to broader matters—a national programme policy, types of material and picture quality really needed, the degree of programme exchange with Europe (or, shortly, with the whole globe), the relative needs and urgencies of other services' demands on ether space, financial questions and many others. Thus it is good to find that the Postmaster General has at last announced the appointment of the long awaited committee to inquire into the future of broadcasting and television in the country; this new committee, under Sir Harry Pilkington, has the broadest terms of reference, covering all aspects of policy. It has been asked by the Postmaster General to consider this present technical report of the Television Advisory Committee; perhaps the new committee will take its technical inquiries a little further too.

Never again, in all probability, shall we in Britain have the opportunity to re-think the whole fundamentals on which our television service rests.

* General Post Office Report of the Television Advisory Committee, 1960. Pp. 20. (London: H.M. Stationery Office, 1960.) 1s. net.

Thus we are forced to reconsider now, for several reasons; Surely we should seize our opportunity and act boldly, with the kind of enterprise and initiative which British industry showed in the 1930's when it took the world lead in television development? At that time we had reached our first point of departure and broke away from earlier television history, with its mechanical standards, to develop a whole new electronics industry. We have surely reached a similar point to-day. For we have the colour-television question forced on us, we have integration with Europe (and we should not restrict this to Europe, but adopt a global view now, with the techniques likely to emerge during the next twenty-five years, being the period under consideration by the Committee), and we have the æther congestion problem; we have a host of new techniques as yet unused.

Something has to be done at this point. Cannot we again break away from tradition and think boldly? We go on transmitting nearly identical frames 50 times a second, to be viewed on traditional (though improved) cathode-ray tubes; Is there no alternative? We go on speaking of wave-bands and other Fourier-like concepts, rather than of probabilities and information-rates. Cannot we devise a new kind of camera with much lower noise figures, and then take advantage of coding schemes? Is it inconceivable to develop receivers with cheap 'memories'? Endless such questions can be raised; it is all very well for a mere academic like myself to raise them, but the overriding question is: Has British industrial inventiveness vanished in this field where once it was so prominent?

The main conclusions of the present report of the Television Advisory Committee may be illustrated by the following table, which defines the four 'bands' which are at present available:

Band	Range (Mc./s.)	
I	41-88	At present used by five B.B.C. channels. Half this range used by four I.T.A. channels. Not at present used, but propagation and other field-trials carried out.
III	174-216	
IV	470-582	
V	606-960	

Nearly half band V has been appropriated already for tropospheric scatter links, leaving only the range 606-800 Mc./s. for possible use for television.

Apart from France, Eire and Britain, 625 lines are standard in Europe, both east and west. It seems wise for us to adopt the same, for our broadcasts will become increasingly integrated with those of Europe (though this is too restricted in my view). The conclusion offered is that, if 625 lines be adopted, the number of alternative programmes offered to the public cannot be increased, unless we spill over into the experimental bands IV and V. Dreams of a third programme begin to fade.

However, the Technical Sub-Committee advises that if television be confined to bands I and III, we could have a third programme working on 625 lines if we limit our channel spacing to 7 Mc./s. This point seems to me to be crucial. For the European standard bands are not 7 but 8 Mc./s., which we are told is needed for full picture quality on 625 lines. How can we get 8 Mc./s. into a 7 Mc./s. pot, and so put three programmes where two stand at present? By compression.

This word 'compression' is not mentioned at all in the present report. Throughout, it is accepted without question that picture quality depends solely upon band-width; it does not. We may not expect the Committee to recommend specific systems of recoding for band-width compression; far too little is understood yet, but it is a thousand pities it has not recommended urgent studies of the subject. Television by present techniques is about as wasteful of band-width as can be; we still have not learnt the lessons of statistical communication theory.

Calculation of signal information redundancy is one thing; invention of techniques for utilizing the results is quite another. Many writers have referred to television signals as being ten-to-one, hundreds-to-one, redundant, but this is going much too far at present. But to compress band-widths in fractional ratios of 7/8 or even, say, 2/3 raises no fundamental difficulties; and there need be no complexity of apparatus in the receiver, for coder and decoder need not be 'mirror-images'.

British industry is doing little about this, to the best of my knowledge. It needs development of new types of low-noise camera and multiplier, of storage systems, of new kinds of time-base particularly. Moreover, the implications of such work extend into many fields other than television. Again, it is conceivably possible to develop systems which would be compatible with existing receivers (by substitution of parts only, such as time-bases).

Whatever changes are proposed, compatibility must be considered, as this report rightly stresses, because some £600 million is tied up in existing receivers in Britain alone. The capital invested in the whole industry is gigantic. This report emphasizes the view so commonly expressed, that 'higher picture quality' necessarily means greater 'detail' (that is, adhesion to realism). If only we could educate the public to accept certain visual conventions and forms, how much we might save by coding techniques! It is a curious divergence, that while modern art does just this, in its abstracting out of reality, our mass-cultures such as television forever seek greater realism like the Victorian painters. This process is to-day very expensive.

COLIN CHERRY

OBITUARY

Prof. W. H. Lang, F.R.S.

By the death of William Henry Lang on August 29 botanists have lost one of the most distinguished plant morphologists of this century. Born in 1874, Lang was educated in Glasgow and entered the University in 1889, where he studied science and medicine, graduating M.B., C.M., with high commendation in 1895. He had in the previous year while a medical student graduated B.Sc. with honours in botany and zoology. In 1900 he graduated D.Sc. and in 1932 the University conferred on him an honorary LL.D. In 1895 he was awarded a Robert Donaldson scholarship which enabled him to work on apogamy in ferns at the Jodrell Laboratory at Kew where D. H. Scott was then keeper. After returning to Glasgow he was appointed lecturer in Queen Margaret College in the University and continued research on ferns and on cycadean sporangia. His work on ferns was undoubtedly stimulated by his association with

Prof. F. O. Bower and his fellow lecturer and great friend Gwynne-Vaughan. He also worked on Hepaticae and published in 1901 a paper on apospory in *Anthoceros*: this was followed by other papers on *Cyathodium*, *Notothylas*. He continued research on Pteridophyta and made important contributions to our knowledge of the gametophytes of the Ophioglossaceae. In 1909 he produced an exceptionally interesting paper on a theory of alternation of generations in Archegoniatae, based on ontogeny, which led to an organized discussion on "Alternation" at the Linnean Society.

His appointment in the same year as first occupant of the Barker chair of cryptogamic botany in the University of Manchester provided him with much greater opportunity for research. Prof. F. E. Weiss, who occupied the chair of botany, was a most sympathetic and helpful colleague, and Lang had practically no administrative work. He gave lectures, only to the honours students, on cryptogams. In 1910 he went on an expedition with A. G. Tansley to Ceylon and Malaya to study tropical Cryptogams. On returning he continued work on the morphology of the Ophioglossaceae and between 1910 and 1914 published four papers in the *Annals of Botany*. In 1914 and 1915 there appeared in the *Memoirs of the Manchester Literary and Philosophical Society* his "Studies in the Morphology of *Isöetes*", probably one of the most difficult subjects on which he had worked. The complex anatomy of the plant and its curious method of growth presented particularly difficult problems. Lang's descriptions are for the most part clear and unambiguous, but it requires close concentration on the part of the reader to follow his com-

parisons between the stelar morphology of *Isöetes* and that of other Pteridophyta. It was perhaps his most notable work up to that date.

The discovery by Dr. W. Mackie, of Elgin, of petrified plants in an astonishingly good state of preservation in chert of Middle or Lower Devonian Age in Aberdeenshire had far-reaching results. The investigation of the Rhynie fossils was carried out by Kidston and Lang. They commenced publication of their results in 1917 in the *Transactions of the Royal Society of Edinburgh* and completed it in 1921, when they gave an account of their discovery at the meeting of the British Association in Edinburgh. These memoirs on the Rhynie plants are models of accuracy in description and restraint in phylogenetical speculation. Lang was aware of the importance and significance of these discoveries and their bearing on problems of evolution and comparative anatomy, but wisely left it to others to indulge in speculation on the course of evolution of vascular plants. Later discoveries by him and others of complex Silurian and Lower Devonian plants fully justify the restraint shown by Kidston and Lang, whose names will always be associated with this, the most important contribution of the century to our knowledge of early plant life.

Those who were privileged to know and work in the same laboratory will remember him as a most exceptionally gifted man with many and varied interests not only in science but also in literature and the Fine Arts. He was extremely friendly and helpful, and his junior colleagues have reason to remember him with great respect and affection.

JOHN WALTON

NEWS and VIEWS

Physiology at Birmingham: Prof. H. P. Gilding

PROF. HENRY PERCY GILDING, who is retiring from the chair of physiology in the University of Birmingham, graduated at Oxford in 1923 and in the same year entered on a distinguished undergraduate and postgraduate career at St. Bartholomew's Hospital Medical College where, while the Department of Physiology was without a professor, he had charge of the teaching of physiology and the administration of the Harvey Laboratories. In 1928 he was a Fellow of the Rockefeller Institute, New York, where he carried out research with Dr. Peyton Rous. He returned to London to join the Physiology Department at University College and in 1932 was appointed reader. At University College he continued his researches on the circulation of the blood and on lymph and his interest in the applications of physiology was shown by his tenure of a research post with the Medical Research Council and the Thomas Young lectureship in clinical physiology at St. George's Hospital Medical School. When he was appointed to the chair of physiology in Birmingham in 1933, Gilding made great use of the opportunities given to him for planning and organization in the building of the new Medical School. He is well known for his interest in medical education, and when teaching in the new School was established, he initiated the scheme of integrated teaching of physiology and anatomy by co-operation between the two Departments which has attracted so much attention.

When the Goodenough Committee was considering developments in medical education he played an active part in obtaining increased facilities for honours courses in physiology for medical students. A great demand for his services as an external examiner is not only a consequence of this interest but also a tribute to his personal qualities. He has for many years given useful service to the Physiological Society as a member and chairman of its Committee, as its treasurer and as its representative on the Council of International Abstracts of Biological Sciences. He served as a member of the Council of the British Association and was recorder and later president of its Section I (Physiology). Gilding saw much active service in the First World War which interrupted his undergraduate career and he was for a time a prisoner of war.

Prof. Ian E. Bush

DR. IAN E. BUSH has been appointed to succeed Prof. Gilding. He went from Bryanston School to Pembroke College, Cambridge, and was awarded first class honours in Natural Sciences Tripos Part 2 (Physiology) in 1949. The grant of a Medical Research Council scholarship in 1949 enabled him to work in the Physiology Laboratory, Cambridge, until 1950, when he moved to the National Institute for Medical Research, where he stayed until 1952. The degree of Ph.D. (Cantab.) was conferred in 1952. A Commonwealth Fund Fellowship provided the opportunity for him to travel to the United States, where he

worked in the Biological Chemistry Department, University of Utah, and later at the Huntington Memorial Laboratory, Massachusetts General Hospital. In 1953 he became a medical student and part-time research assistant to the Medical Unit at St. Mary's Hospital, London. In 1956 he moved to Oxford with Sir George Pickering on the latter's appointment to the regius chair of medicine. He qualified M.B., B.Chir. (Cantab.) in 1957. He was placed in charge of a group for research into humoral physiology and pathology under Sir George Pickering. This work has attracted the support of the Medical Research Council and the Rockefeller Foundation. He has published numerous papers on steroid metabolism and is particularly well known for his able use of chromatography in the analysis of steroids in general.

Science Adviser to the U.S. Secretary of State

DR. WALTER G. WHITMAN, formerly chairman of the Department of Chemical Engineering of Massachusetts Institute of Technology, has been appointed science adviser to the U.S. Department of State, in succession to Wallace R. Brode, who has resigned. Dr. Brode, who has a long record of government service with various scientific agencies, has been serving as science adviser to the Secretary of State since January 1958. A science adviser and a number of science attachés at posts abroad were first appointed in 1951. During his tenure as science adviser, Dr. Brode revitalized the entire science attaché scheme. Ten embassies abroad have been staffed with science attachés, many of whom cover a number of countries on a regional basis. These attachés facilitate scientific exchanges with the United States, and interpret American science to scientists, science writers, editors, and others who influence foreign attitudes toward the United States, and its scientific and technological achievements. Further, as a function of prime importance to the Department of State, they help other members of the embassy staffs to give proper consideration to the scientific and technical factors involved in the decisions they must make.

Dr. Whitman, the new science adviser, served with the National Advisory Commission for Aeronautics during 1940-45, was director of the Lexington Project of the Atomic Energy Commission in 1948, and also served as secretary-general for the United Nations Conference on the Peaceful Uses of Atomic Energy in 1955. He was chairman of the Research and Development Board of the Department of Defense during 1951-53 and was a member of the National Advisory Commission for Aeronautics during the same two years. He is on terminal leave from the Massachusetts Institute of Technology.

British Steel Castings Research Association : Appointments

THE British Steel Castings Research Association, Sheffield, has announced the following new appointments. Mr. C. M. Stoch to be assistant director of research. Mr. Stoch, who joined the Association in 1951, has been in charge of the Plant Engineering and Industrial Health Section since 1953, and for the past two years has also been acting head of the Steelmaking Section. He was born in Poland, and, after having graduated in 1937 in metallurgy at the University of Krakow, he worked in the steel-making department of the Baildon Steelworks, Katowice. He was called to the Forces in 1939 and

took part in the fighting in Poland, rejoined the Polish Forces in France in 1940 and afterwards in Great Britain. Mr. Stoch has recently been investigating the development and improvement of dust control devices on grinding machines and fettling benches. Mr. K. Knaggs, deputy head of the Association's Steelmaking Section for the past two years, has been appointed head of this Section.

Joint British Committee for Electron Microscopy

A JOINT British Committee for Electron Microscopy has been set up with the following three objects in mind: first, to co-ordinate meetings in the whole field of electron microscopy, including the design, use and application of the instruments, and of cognate subjects arranged by its constituent bodies; secondly, to encourage the holding of joint meetings by its constituent bodies; thirdly, to act in the collective interest of the constituent bodies by maintaining liaison with the International Federation of Electron Microscope Societies and with National Societies covering this field, and also by maintaining liaison with overseas societies concerned with electron microscopy. Dr. V. E. Coslett, University of Cambridge, has been elected the first chairman of the Committee. The foundation members are as follows: the Anatomical Society of Great Britain and Ireland; the Physics Group of the Textile Institute; the Biochemical Society; the Royal Microscopical Society; the Chemical Society; the Institute of Physics and the Physical Society; the Society for Experimental Biology; the Iron and Steel Institute; the Society for General Microbiology; the Linnean Society; the Pathological Society of Great Britain and Ireland; the Institute of Metals. Other societies interested in electron microscopy are welcome to adhere to this Committee. Further information can be obtained from the General Secretary, Royal Microscopical Society, Tavistock House South, Tavistock Square, London, W.C.1.

Funds for Basic Research in the United States : 1959-60

ESTIMATES by the National Science Foundation in "Reviews of Data on Research and Development", No. 22, put total funds for basic research in the United States in 1959-60 at 1,000 million dollars, compared with 430 million dollars in 1953-54 and 830 million dollars in 1957-58. Throughout this period funds for basic research were about 8 per cent of the total funds available for research and development. In 1957-58 expenditure on basic research by colleges and universities was 392 million dollars, an increase of 88 per cent on 1953-54, corresponding expenditure by the Federal Government being 111 million dollars (an increase of 136 per cent) and by industry 272 million dollars (80 per cent increase). The Federal Government, however, supplied 423 million dollars of the total funds for basic research and industry 249 million dollars, although these figures represent only 7 per cent of the total research and development funds from each of these sources. Of Federal funds for basic research in 1957-58, the universities and colleges received 57 per cent (compared with 61 per cent in 1953-54), industry 10 per cent (10 per cent in 1953-54), other non-profit institutions 7 per cent (5 per cent in 1953-54) and Federal Government institutions 26 per cent (24 per cent in 1953-54). Of the total 835 million dollars, 282 million dollars went to the biological and 553 million dollars to the physi-

cal sciences, of which 195 million and 197 million dollars, respectively, were in the universities and colleges; for industry the corresponding figures were 27 million and 245 million dollars, respectively; for other non-profit institutions, 27 million and 33 million dollars; and for Federal Government institutions, 33 million and 78 million dollars. For 1953-54, the corresponding figures are: colleges and universities, 92 million and 116 million dollars; industry, 9 million and 142 million dollars; other non-profit institutions, 14 million and 12 million dollars; and for Federal Government institutions, 17 million and 30 million dollars.

The Indian Potato Journal

The Indian Potato Journal, issued by the Indian Council of Agricultural Research (1; April 1959. Ed., P. L. Jaiswal. New Delhi. Rs. 6.00 per annum) as a half-yearly periodical, will be devoted exclusively to the improved cultivation of this crop. The journal contains original scientific papers, general articles and reviews of relevant research. Thus, in Vol. 1, No. 2, there are contributions on such topics as the effect of nitrogen fertilizers on the yield and chemical composition of potatoes; the crossability of diploid *Solanum* species; growth and tuber formation; control of sprouting by growth regulators; Kashmir as a potential seed potato area.

Geodesy and Artificial Satellites

In a recent issue of *Smithsonian Contributions to Astrophysics* (3, No. 9. Pp. iv+95-161. (Washington, D.C.: Government Printing Office, 1960.) 65 cents), entitled "Geodetic Uses of Artificial Satellites", G. Veis gives a detailed mathematical exposition of methods for extracting geodetic information from observations of artificial satellites. Most of the geodetic results so far obtained from satellites have stemmed from their orbital perturbations, this paper lays the foundation for the satellites' other role, when they act as aerial triangulation points and can be utilized directly, without the intervention of dynamical theory. A second recent publication on this topic is "Use of Near-Earth Satellite Orbits for Geodetic Information", by P. D. Thomas (Technical Bulletin No. 11 of U.S. Coast and Geodetic Survey. Pp. ii+36. (Washington, D.C.: Government Printing Office, 1960.) 45 cents). This is a lively and rather informal review of results up to the end of 1959 on the Earth's flattening, which satellites have shown to be $1/298.2$ rather than $1/297$, as previously believed. The paper also discusses the methods of observing satellites and some related topics.

Fluctuations In the Level of the Caspian Sea

The level of the Caspian Sea (*Nature*, 179, 1112; 1957), after many years of fall, in 1957 began to rise in spite of a marked decrease in the inflow of the river water. According to B. G. Richter (*Priroda*, 2, 45; 1960), this rise can be explained by the nature of the tectonic movements occurring in this region, and which tend to alter the volume of the hollow in which the Caspian Sea is situated. A map showing areas of elevation and areas of sinking explains the relative rapid rise of the land in the region of Baku and in parts of the eastern shore of the Caspian Sea, especially the rapid drying up of the salt-producing bay of Kara-Bog haz-Gol (*Nature*, 179, 409; 1957), which is discussed by V. D. Polyakov (*Priroda*, 3, 93; 1960).

Protease Inhibitor In Human Blood

SERUM trypsin and chymotrypsin inhibitors have been determined with reasonable accuracy by a modified ultra-violet absorption method. The serum examined was diluted thirty times with normal saline. N. Aizawa reports in the April issue of the *Yokohama Medical Bulletin* that both inhibitors were found to be stable below 3° C. for about fifty days, and that 20 per cent of trypsin inhibitory activity was maintained even after heating at 60° C. for 30 min. On the other hand, inhibitory activity against chymotrypsin completely disappeared under the same conditions. It seems difficult to conclude that both inhibitory activities are exerted by a single inhibitor. Further experiments showed that the trypsin inhibitory principle was found to pass gradually through a 'Cellophane' membrane; it is probable that the inhibitory factor is a relatively lower molecular substance than hitherto supposed. From the fact that trypsin inhibitory activity was recovered by neutralization, even after the incubation of the serum for 24 hr. at less than pH 5.0, the pH inactivation may be a reversible change.

The Stone Age In Jersey: Saint Brelade's Cave

SAINT BRELADE'S Cave in Jersey, British Channel Islands, has long been known as an important prehistoric site of the Stone Age. Following some preliminary digging it was partially excavated by the late Dr. R. R. Marett in 1913, but the First World War stopped the work, and though it was continued later, the bottom layers were never reached. An important Mousterian industry was, however, unearthed. Recently, Father Christian Burdo has re-examined the site, and excavated the lower layers where he has found an Acheulean assemblage. Dr. Zeuner dates the cave infilling to a period from the end of the Riss glaciation to the start of the Würm. The Société Jersiaise has published an excellent account of the finds which can be obtained from the Museum, 9 Pier Road, Jersey (Excavation of a Pre-Mousterian Horizon, 1950-1958. Pp. 77+8 plates. (Jersey, Ch. Is.: Société Jersiaise. 7s.)). Several of the implements are illustrated, and a list of the fauna and flora found given. There are also some excellent full-page photographs of the site itself.

James Picker Foundation:

Radiological Research Awards

ON behalf of the James Picker Foundation, the National Academy of Sciences-National Research Council is accepting applications for fellowships and grants in the field of radiology and nuclear medicine for the year 1961-62. The awards are made in four categories: *Advanced Fellowships in Academic Radiology*, offered for the first time during the past year, the purpose of which is to prepare the candidate who has completed his or her clinical training in radiology to meet in full the intellectual demands of an academic position in radiology; *Postdoctoral Fellowships in Radiological Research* are open to recent graduates who desire experience and training in scientific investigation, and while these awards are for a period of one year, requests for renewal will be considered; *Grants for Scholars* are a transitional form of support, designed to bridge the gap between the completion of research fellowship training and the period when the young scientist has thoroughly demonstrated his competence as an independent

investigator, and while the initial grants are limited to one year, renewal for two additional years may be recommended; *Grants-in-Aid of Research* are designed to encourage investigations offering promise of improvement in radiological methods of diagnosis or treatment of disease and are awarded to institutions, rather than to individuals. Applications in these four categories will be reviewed by the Committee on Radiology of the Academy-Research Council's Division of Medical Sciences. Final determination of awards is made by the Foundation on recommendation of the Division. These awards are not restricted to citizens of, or laboratories within, the United States. Application forms and further details can be obtained from the Division of Medical Sciences (Room 305, AAUW), National Academy of Sciences-National Research Council, 2101 Constitution Avenue, N.W., Washington 25, D.C. Applications must be submitted by December 1, 1960.

The Royal Institution of Naval Architects

THE Council of the Royal Institution of Naval Architects has made the following awards: *Royal Commissioners for the Exhibition of 1851 Postgraduate Scholarship in Naval Architecture* (1960), £600 per annum for two years, to Mr. B. S. Bowden, of King's College, Newcastle upon Tyne; *The Royal Institution of Naval Architects Scholarship in Naval Architecture* (1960), to Mr. M. A. Cubitt, of Messrs. Vosper, Ltd., Portsmouth (£400 per annum for three years at King's College, Newcastle upon Tyne); *Vickers-Armstrongs Scholarship in Naval Architecture* (1960), to Mr. Brian T. Procter, of Trinity Academy, Edinburgh (£400 per annum for four years at the University of Glasgow).

Naval Radiological Defense Laboratory

THE Naval Radiological Defense Laboratory in San Francisco has created a new position with the title of 'scientist-in-residence'. The scientist appointed will be expected to work on a matter of his own choosing within broad categories of the Laboratory's field of interest, which are the basic thermal and ionizing radiations from all types of nuclear reactions, their chemical, physical and biological effects, both topical and environmental, and ways of predicting, preventing or minimizing them. Candidates should have demonstrated superior ability for creative research. It is a full-time appointment, normally for one year. Two places are available this year; later there may be six. Applications should be addressed to Scientist-in-Residence Committee, U.S. Naval Radiological Defense Laboratory, San Francisco 24, California.

Natural Resources in Scotland

THE Scottish Council's Committee on Natural Resources is holding a symposium on "Natural Resources in Scotland" at the Royal Society of Edinburgh, 24 George Street, Edinburgh, during October 31–November 2. The three days will be devoted as follows: first day, "Basic Resource Facts"; second day, "Utilization of Resources"; third day, "Resource Administration and Development". The chairmen on each of the three days will be: the Rt. Hon. Lord Bilsland (president, Scottish Council, and Development and Industry), Sir Cecil M. Weir (chairman, London Executive Committee, Scottish Council, and Development and Industry),

Sir Edward Appleton (principal, University of Edinburgh). Further information can be obtained from the Organizing Secretary, The Scottish Council (Development and Industry), 1 Castle Street, Edinburgh, 2.

William Thomas Brande

MR. E. E. IRONMONGER, Westminster College, North Hinksey, Oxford, writes: "I am collecting information concerning the life and work of William Thomas Brande (1788–1886), who was professor of chemistry at the Royal Institution during 1813–52 and secretary to the Royal Society during 1816–26. I should be glad to hear of any letters, manuscript material, etc., of which readers of *Nature* may have information".

Announcements

MR. A. V. S. DE REUCK, formerly assistant editor of *Nature*, has been appointed deputy director of the Ciba Foundation for the Promotion of International Co-operation in Medical and Chemical Research, London. Miss M. P. Cameron has returned to the Ciba Foundation as scientific assistant and librarian after five years in the United States.

THE first award of the Ellis Medal of the Institution of Works Managers goes to Mr. W. Huddleston, of the Springfields Atomic Factory, Salwick, Lancs. The Ellis Medal commemorates the work of John Milton Ellis, who helped to establish the Institution's training course, and will be awarded annually to a student of the Institution, under the age of thirty, who, having qualified at the end of the two-year course in works management, satisfies the assessors that he has most fully appreciated the practical implications of the training he has received in the art and science of works management.

At the inaugural meeting of the first British Congress on the History of Medicine and Pharmacy, held in London on September 29, Sir Geoffrey Keynes and Prof. Owsei Temkin were awarded the honorary fellowship of the Faculty of the History of Medicine of the Worshipful Society of Apothecaries of London. The fellowship, which is an exclusive award to be held by no more than twelve at any one time, irrespective of nationality, is bestowed for outstanding services to scholarship in the history of medicine and pharmacy. Sir Geoffrey Keynes, whose work on Harvey, Sir Thomas Browne, John Ray and Robert Hooke is fundamental, is the first recipient of the new honour. Prof. Temkin, who is director of the Institute of the History of Medicine in Johns Hopkins University, Baltimore, has made many erudite studies of classical and medieval medicine, his authoritative monograph on "The Falling Sickness" being the most widely known of his works.

THE Medical Research Council states that in future all requests for compounds in the Steroid Reference Collection should be addressed to Prof. W. Klyne, Chemistry Department, Westfield College, Hampstead, London, N.W.3, and not to the Postgraduate Medical School at Hammersmith.

ERRATUM. Dr. C. W. Beklemishev has written in connexion with his communication entitled "Southern Atmospheric Cyclones and the Whale Feeding Grounds in the Antarctic" in *Nature* of August 6, p. 530; his address should read: "Oceanological Institute, 8 Bahrushin Street, Moscow 127".

PHYSICS EDUCATION

"THE difference between agriculture and farming" (a percipient candidate recently observed in an Ordinary Level General Certificate of Education examination) "is that in farming you actually do it". The gulf separating the doers and the talkers is conspicuous in the field of education, but the teachers who attended the recent International Conference on Physics Education managed to illuminate several important problems with little help from the platitudes so often displayed on such occasions.

Eighty invited representatives from twenty-eight countries formed the membership of the conference, which met at Unesco House, Paris, during July 28–August 4, under the sponsorship of the United Nations Educational, Scientific and Cultural Organization, the Organization for European Economic Co-operation and the International Union of Pure and Applied Physics. Prof. Sanborn C. Brown of the Massachusetts Institute of Technology was in the chair, and Mr. Norman Clarke of the Institute of Physics was secretary of the conference.

The main topics on which discussion centred were: (a) the need for instruction in physics from an early age (seven years was proposed without dissent); (b) the inadequacy of present-day methods of teaching physics in European and North American schools; (c) the difficulties found in trying to introduce Western educational ideas into Oriental countries; and (d) the need for radical innovations, exemplified by the concurrent exhibition of new teaching aids and the fully documented account of the Physical Science Study Committee's work in the United States.

The proceedings opened with a vigorous iconoclasm, presented by a working party appointed to examine the teaching of physics in schools. It found that contemporary physics courses in most European countries involve no scientific knowledge that has been discovered during the past few decades. Generally they offer a number of so-called facts and laws, combined with simple but pointless experiments to form "a somewhat desiccated and often strongly mathematical course based upon a few elementary physical principles". The presentation of physics in schools was condemned for failing to exploit the natural curiosity of children about the world in which they live, or to recognize their present-day familiarity with outstanding examples of applied science.

Strong criticism was expressed of physics courses intended primarily for the instruction of future specialists and of the truncated fragments which are all that can be acquired by pupils who leave school at sixteen. It was agreed that physics should be taught to all pupils and that the needs of those who do not intend to specialize must predominate. Neglect of this requirement was blamed for the drift towards a world of two cultures with a false antithesis between sciences and humanities. Lack of time was not regarded as a justification for early specialization. On the contrary, it was insisted that future specialists would be all the better for an early course of a broader kind and that a couple of years after the age of sixteen should provide ample time for additional instruction to meet university entrance requirements.

Discussing the content of an ideal physics course, the conference affirmed the basic position of mechanics, but recommended that it should be taught as a science, with a constant appeal to Nature, and not allowed to degenerate into a branch of applied mathematics. The child's introduction to physics should be through a consideration of atoms, molecules and electrons, rather than by the customary study of mechanics and hydrostatics. Practical work, it was suggested, should become more realistic, though the changes needed cannot be defined without further investigation. The proportion of time spent on practical work done by the pupils (about half all the time devoted to physics) in many English schools was judged to be excessive, particularly since much of it involved merely the measurement of standard quantities by methods possibly of historical interest, but of no use to the practising physicist.

Having diagnosed the malady and prescribed the treatment, the conference acknowledged the shortage of teachers qualified to administer it. Low salaries were reported as a major discouragement in some countries, though improved scales did not always have any obvious effect on recruitment. Working conditions, opportunities for advancement, contact with other scientists and—perhaps most of all—social prestige were named as factors influencing the choice of a career among those who might be attracted to teaching.

European and American ideas on the teaching of physics in schools and universities have been adopted with varying degrees of success in other parts of the world. After the proclamation of the Turkish republic nearly forty years ago, many drastic reforms were accomplished in the desire to break away from the old philosophy and to embrace Western ideas. In this movement the encouragement of scientific studies was important both in aiding the country's industrial development and in promoting the attitude of mind favourable to the absorption of Western culture. Educational methods drawn from British and American experience are combined in the system now used successfully for the teaching of physics at school- and university-level in Turkey.

Japanese delegates told a different story. When their country first embraced Western civilization, nearly a century ago, physics was made a compulsory subject in high schools and retained this status until 1948. By then an educational mission from the United States had reported unfavourably on the exaggerated respect for authority inculcated by the prevailing system of teaching which, in physics, involved cramming from a text-book with little experimental work. Under the new dispensation, the study of physics in high schools was made optional and was promptly abandoned by two-thirds of the senior pupils. For several years the school curriculum included only one science subject, in which the university entrance examination was also taken. Many pupils offered biology—which they thought to be easily learned—even though intending to study physics or engineering at the university. Some universities, in defiance of the Ministry of Education, started their own entrance examinations in physics to ensure that students were adequately prepared.

Public opinion supporting this stand, the high school curriculum was modified in 1956 to include two science subjects, and the enrolment in physics has now increased from 33 per cent to 75 per cent. Nevertheless the present arrangements for teaching physics in Japanese schools were reported by Haruo Ootuka (Tokyo) to be "almost completely unsuccessful".

The Western traditions which form the basis of these experiments are themselves under close scrutiny in the United States, where the Physical Science Study Committee has spent 5,000,000 dollars since 1956 on the preparation of a radically new curriculum for high school physics. The Committee's syllabus, intended for a one-year course to pupils aged 15-17 years, discards much that has been familiar to teachers and students during the past half-century, offering instead a penetrating analysis of selected topics contributing to a logical picture of the universe. The student who follows the course will know little about hydrostatics, the tangent galvanometer or the compound pendulum—but he will have measured the thickness of a tissue by counting interference fringes, he will have studied the Franck-Hertz experiment on atomic energy-levels, and he will have a working knowledge of vector kinematics.

Text-books and laboratory guides are supplemented by a large collection of films, some still in preparation, and by a series of paper-backed books.

Apparatus for experiment and demonstration is being manufactured at modest cost by an American scientific instrument firm.

More than 30,000 students have taken the course in its preliminary versions. A considerable expansion of the programme is expected when the literature and other teaching aids become available on a large scale towards the end of 1960.

Many ideas brought forward in the discussions were underlined in the exhibition of apparatus, arranged by G. R. Noakes (Uppingham). The United States, Britain and France provided most of the material on view, but interesting contributions came from a few other European countries. Manufacturers showed real ingenuity in devising simple apparatus for studying and illustrating the principles of contemporary physics.

Speaking in Brussels on April 27, Lord Hailsham asked: "Can we feel sure that, in evaluating the methods of science teaching now in use, and the possible way in which they might be improved, we are ourselves approaching the matter scientifically? Can we be sure that we are practising what we preach?" The International Conference on Physics Education has helped to answer this question. Further gatherings, perhaps with more limited objectives, would make a modest but distinctive contribution to the cause of education. J. M. A. LENTHAN

SEVENTH CONGRESS OF THE INTERNATIONAL SOIL SCIENCE SOCIETY

THE seventh Congress of the International Soil Science Society was held at Madison, University of Wisconsin, under the presidency of Prof. Richard Bradfield of Cornell University, during August 15-23, with the motto "Promote Peace and Health throughout the World by alleviating Hunger through Soil Science". In the seventh Congress, sixteen hundred delegates, representing more than fifty countries, assembled and discussed nearly four hundred original contributions on different aspects of soil science and soil improvement in seven commissions or divisions. Moreover, there were seven general lectures and one symposium on tropical soil resources under the Food and Agriculture Organization. In the opening session on August 15, the members of the Congress were welcomed by the Governor of Wisconsin and the president of the University, and addresses were delivered by the director-general of the Food and Agriculture Organization, Mr. B. R. Sen, Prof. Bradfield and Dr. C. E. Kellog, the vice-president of the Congress.

Three tours were organized in which the activities and achievements of the universities and Government Departments of the United States in agriculture and soil conservation were demonstrated. Numerous soil profiles in many parts of the country were intensively studied and photographed. Lysimeter tests were exhibited at the soil and water conservation research station at Coshocton, Ohio.

The chief topics for study and discussion at the Congress were: soil classification, cartography and maps of soils, soil physics, moisture retention, irrigation, fertility, structure, morphology, soil

chemistry, analysis, diagnosis, organic matter, humus, composts, soil fauna and soil formation, micro-organisms, interaction of organic and inorganic matter in soils, clay minerals, genesis, the use of isotopes, liming, fertilization by nitrogen, phosphate, potash, trace elements, management of forest soil, saline soils, alkaline soils, etc.

Dr. F. E. Bear, a leader of soil science in the United States, in his report on "Soil in Relation to Nutritional Needs in Foods", stated that man can effect organic and mineral nutrient balance in his diet by taking a variety of plant products from many soils and meat, eggs and milk, but unfortunately such a selection is not always possible. Dr. G. D. Scarseth reported that the soils of humid tropics are highly leached and are poor, and when cleared for farming have to be adequately fertilized. According to Dr. K. H. Schutte and S. Amdurer, trace-element deficiency is widespread in South Africa. Dr. W. H. Allaway claimed that there is little evidence of harmful results from chemical fertilizers as envisaged by the late Dr. A. Carrel in his book "Man the Unknown".

In an important paper on the "Relation of Radioactive Contamination of Crops to Soil Fertility", Drs. R. F. Reitemer and R. G. Menzel stated that the hazard associated with accumulation in the soil of the shorter-lived fission products, for example, iodine-131 and barium-140, is slight, but longer-lived isotopes like strontium-89, strontium-90 and caesium-137 are more dangerous. Addition of large amounts of organic matter to soil reduces the uptake of radio strontium and calcium. Prof. E. Turog

described the development of soil testing methods in the United States during the past fifty years.

A large number of important communications on soil nitrogen, nitrification, nitrogen fixation, soil humus, composts, loss of nitrogen from soils, residual fertility, etc., were taken up in several sections of the Congress, because it is well established that nitrogen is the key element in cereal and other food production. Field trials in temperate countries show that one pound of nitrogen applied produces 16–17 lb. of cereals or other tillage crops, while in tropical countries the production is ten times the nitrogen input. This increase seems to be determined by the humus content in the soil; the soil humus is greater in cool countries than in the tropics. It has been estimated that approximately 1,000 million tons of grains, including corn and 700 million tons of other food materials, are produced in the world at present. This food production requires 100 million tons of combined nitrogen. But the chemical nitrogen industry is providing 7 million tons, legumes 5 million tons, precipitation about 5 million tons and farmyard manure about 2 million tons in world agriculture. In the United States 1.5–2 million tons of chemical nitrogen, 2 million tons of legume nitrogen and perhaps 1 million tons of farmyard manure nitrogen are applied, although approximately 15 million tons of nitrogen are taken out annually from the 510 million acres of agricultural lands. Hence even to-day the majority of the nitrogen need of world crops is being met by the soil nitrogen, which must be augmented in permanent agriculture. One of the easiest methods of increasing the soil nitrogen is to plough in straw after removal of grains, cornstalks, dung, grasses, legumes, etc., mixed with 50–100 lb. phosphate (as Thomas (basic) slag) per acre, as advocated by Prof. N. R. Dhar in the Congress and elsewhere. In this manner 100 lb. of atmospheric nitrogen can be fixed per acre of land and this method is applicable to both tropical and temperate countries, which require an interval of 100–150 days for adequate nitrogen fixation and liberation of available nitrogen, phosphate and potash for crop-growth in these lands.

In this connexion, it is of interest to record that the British Association for the Advancement of Science meeting held in 1949 and presided over by Sir John Russell concluded that only 3 per cent of world food production could be attributed to artificial nitrogen. Moreover, as the application of phosphates increases the yield of crop to the extent of 5–7 times the amount of phosphorus incorporated in the soil, a very large number of papers on phosphorus availability, placement, etc., were considered at the congress.

In reaching Madison, Wisconsin, via Tour 1 and leaving Madison via Tours 2 and 3, the delegates passed through the heart of the Corn Belt, located in the twelve North Central States, which occupy the upper portion of the Mississippi Valley. The United States produces more than half the world's maize and soy beans, and approximately one-sixth of the wheat. The bulk of these is produced in the prairie soils rich in nitrogen and humus, obtained by the natural incorporation of tall grasses in the land and by absorption of sunlight at the surface soil. It seems that no other large area in the world equals these parts of the United States as regards favourable conditions of soils (prairie, chernozem and grey-brown podzolic) and climate for the production of crops. The State of Iowa is the main producing area for maize and pork, Illinois for soy beans, Wisconsin for hay and canning crops and dairy products, which form one-seventh of the milk and half the cheese produced in the United States. The legume alfalfa (lucerne) is the main hay crop and is extensively grown.

The representatives of soil science, from many countries, including the U.S.S.R., Japan, China, India, South Africa, Ghana, Sudan, Congo and all European nations, assembled in Madison, and carried on deliberations in a cordial and friendly atmosphere for creating new knowledge, leading to the progress and welfare of the common man in the world and contributed to international friendship, co-operation and stabilizing world peace.

N. R. DHAR

SOIL SURVEY IN THE WEST INDIES

UNDER the general direction of Dr. T. A. Jones steady progress has been made with the soil survey work of the Regional Research Centre of the British Caribbean, which has its headquarters at the Imperial College of Tropical Agriculture in Trinidad. The first three monographs to appear, namely, "The Parish of St. Catherine, Jamaica", "The Rupununi Savannas of British Guiana", and "St. Vincent" were reviewed in *Nature*, 184, 27 (1959). A further seven have now been published, covering another four of the parishes of Jamaica (St. Andrew, Clarendon, St. James and St. Mary), two further groups of selected areas in British Guiana and the island of Grenada (with Carriacou)*. Two other parishes of Jamaica are reported as completed, leaving six to be done. Each memoir follows the same plan, and as each is intended to be used as a self-contained guide there is a large amount of repetition. Each is

divided into three parts: (1) Factors affecting land use (climate, geology and lithology, relief and drainage, the people and their agriculture, present position of services); (2) the soils and their capabilities; (3) recommendations. Each monograph has a soil map in a pocket and for Jamaica the scale of 1 : 50,000 has been adopted; for Grenada the rather strange scale of 1 : 18,750 has been used. The use of a series of tints and symbols in red over a black outline has enabled much detailed information to be shown on the maps with, doubtless, a minimum of expense.

Although called a "Soil and Land-Use Survey" the existing land use has not in fact been surveyed: throughout, the aim is the severely practical one of relating potential use to soils. It is interesting to note that this has led to the re-use of the older approach to soil study—the grouping of the soils according to parent geological material—since it is found that this has the closest bearing on potential. Soil series are named and used, but take a subordinate place. In fact, Dr. Jones has given his reasons

* Regional Research Centre of the British Caribbean at the Imperial College of Tropical Agriculture, Trinidad, W.I. Soil and Land-Use Surveys. Monographs 4–10. 1959–60.

elsewhere (*J. Soil Sci.*, 10, 196; 1959) why the soil-profile should be abandoned as a basis of classification since soil is "essentially a part of the landscape".

It is almost inevitable, as well as desirable, that this sustained and intensive soil work in the tropics should give rise to serious heart-searching among soil scientists. At one extreme are those pedologists who contend that soils should be studied *quâ* soils, without any consideration for their economic use, and some who even consider only 'natural' soils should be mapped, and that those where pedogenic processes have been impeded by cultivation should be ignored. At the other end of the scale are those who urge that a soil map or a soil study has little value *per se*, unless related to the potential use of the land. At this end of the scale the extreme position is taken, as by Basil Furneaux, that there is little use in mapping at all and that the only useful approach is the *ad hoc* investigation of a soil in relation to its

specific utilization. The West Indian work is nearing the latter approach, except that detailed mapping has been combined with full laboratory investigation. Each soil type which is mapped is given in tabular form a recommended cultivation practice. It is hoped the farmer will not be alarmed to find his land requires, for example, PS/3 ND/VW, which means contour ploughing in three strips, with two in cover but no drains though with vegetative barriers and stone walls. Next he is told what crops out of some 15 may be grown, and warned of special hazards, peculiarities and nutrient requirements.

Most of the West Indian islands have problems of severe population pressure on land resources, and here is a scientific approach to the solution. But how far will the recommendations be followed? How successful would they be? It is too much to hope that they will be applied experimentally over some considerable test areas? The proof of the pudding must be in the eating. L. DUDLEY STAMP

THE AUSTRALIAN ATOMIC ENERGY COMMISSION

STEADY progress is the keynote of the seventh annual report of the Australian Atomic Energy Commission. The report, which covers the financial year ended June 30, 1959, was presented to the Senate on March 10, 1960, by Senator W. H. Spooner, the Minister of State for National Development, who stated that earlier years had been years of innovation and trial as one new activity or another was begun in furtherance of the Commission's objectives, but, as the report shows, that phase had now been left behind*.

The report is divided into seven sections dealing respectively with the search for uranium; uranium mining; raw materials including beryllium and thorium; the research programme; prospects in Australia and overseas for nuclear power; international agencies and conferences; and general activities. The financial accounts and details of research contracts, postgraduate research studentships and undergraduate scholarships, in addition to a list of the Research Establishment buildings at Lucas Heights and of the members of the staff of the Commission, are given in six appendixes.

Air-borne surveys for uranium were on a smaller scale than in previous years, because of a shift in emphasis from uranium search to regional geological mapping, and a contraction of air-borne work in general. At Rum Jungle a detailed programme of geochemical testing was carried out to the west, north-west and south of the mine, and the area was systematically explored for additional ore. Five discoveries of radioactive minerals were reported to the Commission during the year, but none proved significant as possible sources of production.

The production figures given in the report for operations at Rum Jungle show that the uranium section of the plants proceeded satisfactorily, although the production of oxide was only about three-quarters of that during 1958 because of lower grade of head feed to the treatment plant. Two companies, the United Uranium N.L., and the South Alligator Uranium N.L., both operating in the South Alligator River

area, concluded an arrangement with the United Kingdom Atomic Energy Authority for the sale of uranium oxide to the United Kingdom of a total value of approximately six million pounds. The United Uranium's contract, of approximately five million pounds, is for the delivery of oxide during May 1959 and December 1960, and the South Alligator Uranium's contract for the delivery of the remainder during August 1959 and early 1961.

The report comments on the fact that there is at present a world surplus in uranium and that the lull in demand foreseen for the decade 1960-70 sets problems for the Australian mining industry which is now in steady production and which has sufficient ore reserves to fulfil current contracts and to meet Australia's domestic requirements until about 1980. The Commission wishes to maintain an active mining industry in order that new reserves may be developed and to ensure that Australia's long-range needs may be met. It is therefore important that producers should secure overseas markets for their output during the late 'sixties, but in accordance with the Commonwealth Government's principles the exports must be strictly for peaceful purposes. The stockpiling of monazite was continued, but some relaxation on export was allowed. Export of beryllium ores and concentrates remained prohibited.

New buildings to provide additional permanent workshop and laboratory space at Lucas Heights were started during the year under review. These included a large metallurgy/engineering building, a special building for beryllium research, and another devoted to isotopes and technical physics. The reactor *Hifor* was taken up to full power, after two years of calibration and testing, and although the reactor is primarily a materials testing reactor, it has begun also production of radioisotopes for medical, scientific and industrial use. Australian industry is still hesitant in adopting radioisotope techniques, but some improvement was reported during the year. In the reactor physics section theoretical investigations were carried out with the aid of computers on the slowing down of neutrons in beryllium and graphite, and the variation with neutron energy of

* Commonwealth of Australia, 1960. (Sydney: Australian Atomic Energy Commission, 1960.)

absorption in thorium was studied in relation to conversion factor, that is, breeding uranium-233 fuel from thorium. The technical physics section provided additional safety instrumentation for *Hifar* and designed and constructed a wide variety of instruments for nucleonic and physical measurements. Generally, more emphasis was placed on the high-temperature gas-cooled reactor project than on the liquid metal cooled reactor system since it was shown that this system would require a longer period of development. Work on liquid metals was largely restricted to sodium technology required for *Hifar* irradiations. Optimum conditions for the vacuum hot-pressing of reduced beryllium powder and electrolytic powder were established, and laboratory-scale extrusion processes for beryllium metal were developed. Research on the impregnation of graphite with furfuryl alcohol to produce graphite of very low gas permeability was carried out, and a number of sample fuel elements of uranium and thorium dispersed in a diluent were prepared.

The number of staff at the Establishment rose from 295 to 484 during the year, but there was difficulty in recruiting research officers of the required ability and experimental officers. The Commission was

represented at the inaugural meeting of the council of the Australian Institute of Nuclear Science and Engineering which was held on December 4, 1958, and at the Second International Conference on the Peaceful Uses of Atomic Energy in Geneva. The major publication during the year under review was "Australian Atomic Energy Symposium, 1958", the record of the proceedings of the symposium on the Peaceful Uses of Atomic Energy in Australia, held in Sydney during June 1958. Other publications included the booklet entitled "An Introduction to Nuclear Science", prepared at the request of the New South Wales Department of Education as a teaching aid in schools, and the quarterly journal *Atomic Energy*. A total of approximately £A.30,000 was provided for extramural research contracts to universities. Thirty-five separate research programmes were being undertaken in eight universities and two hospitals and except for a few which were held up by staffing difficulties they were making good progress. Several were nearing completion. No new undergraduate scholarships were awarded, but fifteen undergraduate students continued their training in addition to forty postgraduate research studentship holders.

PUBLIC OPINION POLLS IN JAPAN

PUBLIC opinion polls are an item of American culture which the Japanese have adopted since Hiroshima. "At the height of their popularity during 1946-50 polling agencies in Japan conducted surveys on everything from attitudes towards the Emperor, housing and daylight saving time, to telephone service, prostitution, school lunches and Typhoon 'Jane'". Dr. Matsumoto, who is chief of the Department of Medical Sociology of the Atomic Bomb Casualty Commission, is very well aware of the limitations of this kind of democratized publicity, but he has had the interesting idea of investigating how far this widely ranging material displays a consistent pattern which is in contrast to the ethos of traditional Japanese society*. He considers four main fields of opinion: attitudes towards family and sex relationships, attitudes towards occupation and labour, attitudes towards village life, attitudes towards political leadership.

* Contemporary Japan: the Individual and the Group. By Yoshiharu Scott Matsumoto. Transactions of the American Philosophical Society. New Series, Vol. 50, Part 1. Pp. 75. (Philadelphia: American Philosophical Society, 1960.) 2 dollars.

After a brief description of the orthodox values of the traditional society, Dr. Matsumoto gives the results of a large number of opinion surveys dealing with such questions as: Should an individual choose his own marriage partner or should the parents decide? Do you feel that abortion should generally be permitted? Is there a social necessity for organized prostitution? Do you think the labour unions are protecting the interests of the workers? How do you feel about the abdication of the present Emperor? The book ends with an "Interpretation and Summary" which is sensible but not profound. It scarcely needed a study of this scale to discover that "Japan has been under strong pressure to conform to Western ideology in her post-war situation. On one hand individualistic orientations are heralded; on the other communistic values are proclaimed". There is a good deal of such writing, but so long as Dr. Matsumoto evades the pressure to conform to the clichés of American sociology he is quite fascinating. The bibliography of Japanese sociological studies at the end of the book should be very useful to specialists.

EDMUND LEACH

MASS DENSITY NEAR THE SUN

IT has been known for many years that there is a close relation between the gravitational force of our Galaxy near, and perpendicular to, its plane, the distribution of stellar velocities and the density distribution of matter. The classical investigation of this subject was made by J. H. Oort in 1932, and a number of other investigations have been made since that time.

E. R. Hill has recently published (*Bull. Astron. Inst. Netherlands*, 15, No. 494, 1; 1960) a comprehensive discussion and a new analysis of the available data. His work is based on stars of type K; this

type was chosen because K-type stars occur in relatively large numbers at high galactic latitudes and statistical data on their brightness and motions are much more complete than for other kinds of stars. The velocity distribution of the stars perpendicular to the galactic plane has been represented as the sum of three components, two of low velocity and one of high velocity. The distribution of velocities parallel to the plane was studied as a function of height above the galactic plane. The distribution of giant K-stars was derived from the observed distribution of all stars of type K by using the observed

total proper-motion distributions of *K* stars to assess the proportions of giants at various apparent magnitudes.

All this information was then combined to yield the force of attraction of the Galaxy perpendicular to its plane, in the solar neighbourhood, as a function of distance from the plane. Finally, the total density of matter in the plane of the Galaxy near the Sun was calculated. The result is 9.2×10^{-24} gm./cm.³, or 0.13 solar mass per cubic parsec. This is somewhat larger than obtained by Oort in 1932.

Hill's work suffers from the disadvantage that for distances of more than 500 parsecs from the galactic plane the force obtained conflicts with the requirements of Poisson's law.

In another paper, J. H. Oort (*Bull. Astron. Inst Netherlands*, 15, No. 494, 45; 1960) re-determines the force so that it is consistent both with the observational data assembled by Hill and with Poisson's law. He obtains 0.15 solar mass per cubic parsec for the density of matter in the solar neighbourhood, in excellent agreement with the result of Hill.

DWARF MISTLETOES

A COMPREHENSIVE account of morphological aspects of the parasitism of dwarf mistletoes (*Arceuthobium* spp., Loranthaceae) on North American conifer species has been given by J. Knight (*Univ. California Pub. Bot.*, 30, No. 5, 337; 1960). Some of the literature, terminology and main features of the development of these parasitic plants are critically reviewed and new observations submitted relating to *A. americana* and other species. At the time of penetration into the host the radicular apex loses its histological organization and becomes resolved into simple uniseriate filaments. Such filaments eventually become vascularized endophytic strands. It is possible that all radial sinkers and some aerial shoots may take their origin directly from uniseriate filaments.

All species of *Arceuthobium* may at maturity show a localized distribution pattern of the endophytic system and shoot emergence from the host. Such infections are in some cases associated with brooming phenomena of the tree. In addition, some species when infecting certain hosts induce a remarkable brooming response where the endophytic system keeps up with longitudinal host extension and where a great regularity of shoot emergence prevails. This is described as 'isophasic' parasitism.

There are recognizable differences in isophasic behaviour among species in which it occurs. These differences involve the position of mistletoe shoots in relation to host organs, dominance and precociousness of mistletoe shoots at the girdles, duration of reproductive activity, and so on. A mistletoe species causing an isophasic response on one host species may not do so on another; similarly, a tree when infected by one mistletoe may form an isophasic broom, whereas infection by a second species may result in an entirely different type of parasitism. The isophasic capacity does not therefore reside solely in either host or parasite, but is the result of mutual interaction. The endophytic system is most extensively developed in isophasic brooms. In those of *A. americana* on *Pinus contorta* and of *A. douglasii* on *Pseudotsuga menziesii*, the ultimate filaments are present in the apical meristems of the host branches and probably remain there throughout the yearly growth-cycle. In the latter broom, an actual emergence of endophytic filaments takes place just above the youngest bud scales. The author suggests that the endophyte may be present in the apical meristem of the host branches of all isophasic brooms, and that such presence in the host apex is a corollary of regularity in shoot emergence.

FACT AND FICTION ON THE BREEDING OF THE WANDERING ALBATROSS

By DR. R. CARRICK, K. KEITH and DR. A. M. GWYNN

Wildlife Section, Commonwealth Scientific and Industrial Research Organization, Canberra, and Australian National Antarctic Research Expeditions, Melbourne

THE reputation of the wandering albatross (*Diomedea exulans*) as a parent has suffered on occasion at the hands of the ornithologist, professional and amateur alike. The starvation theory held that the young albatross was fed from hatching in March until about June, and then deserted throughout the Antarctic winter while it subsisted on reserves of stored fat. Some writers state or imply that there is no resumption of parental feeding before the fledgling takes wing about December; others cite observations of feeding, or of fresh food in the nestling's stomach, in spring. The relevant evidence and opinions of successive writers are:

1865. Hutton¹ stated that Harris at Kerguelen saw no adults between June and October, and no feeding from October onwards.

1866. Andersson² quoted the opinion of a sealer that young albatrosses live on their own fat after being abandoned by the parents.

1891. Chapman³ stated that Fairchild observed albatrosses, nearly all young, on the islands below New Zealand in October, 1890, and concluded that the large full-grown chicks are abandoned and live on their own fat until they fly.

1905. Buller⁴ quoted Buckland, who visited islands to the south of New Zealand, to the effect that the

Fig. 1. Growth curves of five young wandering albatrosses at Macquarie Island during 1956

nestling becomes so fat that it exceeds the full-grown adult in weight, and is then deserted for at least four months until October.

1929. Matthews⁵ spent the winter of 1925 at South Georgia and identified *Nototheniid* fish in the stomachs of young wandering albatrosses in early September; at that time the parents return about once a day and remain only a few minutes to feed the nestling. From observations in November and December 1925 and January 1926, Matthews concluded: "The adult albatross do not breed every year, as they do not finish feeding their young until after the new season's eggs are laid (by other birds) and incubation has started. Consequently there must be an interval of at least one season between the consecutive matings of any one bird".

1936. Murphy⁶, who visited South Georgia during December 1912–February 1913, stated: "With the setting in of the antarctic autumn, the adult albatrosses completely abandon their nestling offspring, not for a matter of days or weeks but forever". (An extravagant misstatement in view of Matthews's evidence.) He found several young with empty stomachs shortly before they were due to fledge.

1951. Rankin⁷ observed a breeding colony at Albatross Island, South Georgia, during December 1946–March 1947. On the assumption that the rate of increase in weight at the end of March would be maintained, nestling weight at the end of June was estimated at about 27–31 lb., and considered to be "far in excess of that of the adult"; the heaviest adult male weighed was 26½ lb., and the average of fourteen adults was 23 lb. He concluded that "by finishing with their family cares in June or July, the parents have a clear four or five months before the beginning of the next breeding season, so it is possible for them to reproduce every year". His caption of Fig. 42 is: "Throughout the long Antarctic winter the young albatross is tended by its parents".

1951. Matthews⁸ re-stated his previous evidence and conclusions, referred to "a year of devoted care" by the parents, and stated "at most they can breed only every other year".

1952. Richdale⁹ fully reviewed winter feeding of young wandering and royal (*D. epomophora*) albatrosses, establishing beyond doubt that it occurs in the latter species, and quoting Turbott's observation of wandering albatross chicks being fed early in November 1950 at Antipodes Island.

1953. Paulian¹⁰ observed and photographed feeding at Kerguelen during August and September.

1954. Fisher and Lockley¹¹ discussed the starvation period of nestling *Procellariiformes*, and agreed with Richdale⁹ that *D. exulans* has little, if any.

1958. Jameson¹² stated: "Facts about the all-important period from May to November—the Antarctic winter and spring—are lacking". "... but I believe, with Matthews, Murphy and Rankin, that the young are abandoned for several months" (not at all fair to Matthews). Jameson does not refer to Paulian¹⁰.

1960. Tickell¹³ studied the wandering albatross at Bird Island, South Georgia, during October 1958–March 1959. In November–December "nestlings being handled frequently regurgitated large fresh meals and the sight of the adults feeding young was fairly common". Despite the evidence^{5,8,9,10,13} for feeding of chicks every month from August onwards, Tickell computed a hypothetical weight which the nestling would have to attain by July in order to fledge at the December weight without further feeding. This is based on the physiologically dubious assumption that the unfed downy chick during winter might lose weight at the same rate as the large feathered chick in summer. He concluded that "the evidence now available clearly indicates that the young are fed throughout the fledgling period".

By 1953, if not by 1929, the starvation hypothesis had become untenable, on five counts. Matthews⁵, Turbott (in Richdale⁹) and Paulian¹⁰ had published evidence of feeding during August–December. Richdale's⁹ detailed and accurate study of the royal albatross, and the well-known life-history of the king penguin (*Aptenodytes patagonica*), had shown that the other two sub-Antarctic sea-birds, the young of which develop throughout winter, do not neglect them. The energy requirements of a non-hibernating and growing bird, in this cold environment, must be very considerable indeed, and necessitate regular replenishment. Hormonal control of the annual cycle in birds precludes suspension of parental feeding behaviour for a lengthy period; a break with the proximate stimuli involved causes birds either to

Fig. 2. Adult male wandering albatross (C.S.I.R.O. band number 140-00149; colour-bands red-orange) feeding its own chick at nest No. 2, Macquarie Island, on July 26, 1956

revert to the onset of breeding or to proceed to the next phase, usually the moult. Ornithology offers no precedent for temporary cessation of parental care; so novel a suggestion requires undeniable proof.

Throughout 1956 Keith (biologist, Australian National Antarctic Research Expeditions) kept records of the development of wandering albatross nestlings at Macquarie Island. The five growth-curves (Fig. 1) show the increase in weight during winter; and Fig. 2 shows a young albatross being fed on July 26.

Tickell¹³ also discussed whether adults feed their own or random chicks, a point on which there can be no doubt if the birds are marked. In view of the mounting evidence on this subject, of which only Sladen's¹⁴ study of the Adelie penguin (*Pygoscelis adeliae*), the young of which form crèches, need be mentioned in addition to Richdale's⁹ proof in the case of the royal albatross, it would be surprising indeed if the original parent-nestling bond were not maintained. Many observations of banded birds at Macquarie Island confirm that wandering albatross parents feed only their own young, but nests there are much more widely spaced than at Bird Island. Tickell's¹³ final conclusion, "... it must be held that the wandering albatross, like the royal albatross, breeds only once every two years", also requires birds, the identity, and history during several years, of which are known. Matthews's^{5,8} conclusion (quoted above) on similar evidence is more carefully correct. Since 1954, 48 adults and 37 young have been banded on Macquarie Island; frequency of breeding follows the pattern established by Richdale⁹ in the royal albatross, namely that successful pairs breed in alternate years and early nest failures enable the next attempt to be made the following summer. Constancy of site and mate is the rule. The full results of the Macquarie

Island studies are included in an Australian National Antarctic Research Expeditions report on the birds of this Island to be completed during 1961.

The wandering albatross is a noble bird which has long excited the imagination of poet, voyager and scientist, but canards ill become it. In 1929, after spending a full year at South Georgia and studying large wandering albatross colonies at the end of August, September, November to January, and March, Matthews⁵ produced the evidence and correct conclusions on both winter feeding of the young and non-annual breeding of successful parents. Subsequent writers up to 1960, after at most a summer contact with the bird, have done his work less than justice. The time has come to consign much past writing on the wandering albatross to the limbo of ornithological mythology, and to replace speculation with the direct evidence, based on individual identification whenever possible, which modern ornithology demands.

CHEMISTRY OF VISUAL ADAPTATION IN THE RAT

By JOHN E. DOWLING

Biological Laboratories, Harvard University, Cambridge, Mass.

Rhodopsin Concentration and Visual Sensitivity

THE loss of visual sensitivity after light adaptation, and the recovery of sensitivity during dark adaptation, are common phenomena. Hecht was the first to emphasize the idea that these processes represent the bleaching and synthesis of visual pigment. However, until very recently, experimental attempts to formulate the relationship between visual pigment concentration and visual sensitivity or threshold have not been fruitful, principally because in man, in whom visual thresholds are most commonly determined, pigment concentrations cannot easily be measured. In experimental animals, on the other hand, pigment concentrations can readily be measured, but special means must be employed to estimate visual thresholds.

Recently, in a study of vitamin A deficiency in rats¹, I used the electroretinogram to assay retinal function and sensitivity. I found that the electroretinogram threshold of the eye rose regularly and linearly with time on the deficient diet, similar to the rise of psychophysical thresholds in studies of human

vitamin A deficiency². When the measurements of electroretinogram threshold in the deficient rats were compared with the rhodopsin concentrations in the retinas of the same animals, it was found that the logarithm of the electroretinogram threshold rose linearly with fall in rhodopsin concentration.

I have now extended this analysis to light and dark adaptation. That one can use the electroretinogram to reflect the sensitivity of the eye has been demonstrated by several workers^{3,4}. The most familiar way to do this is to evaluate the change of the electroretinogram during dark adaptation on the basis of stimulus response curves, so estimating the light intensities needed to elicit constant electroretinogram responses. I achieved essentially the same result by measuring, at various times during dark adaptation, the brightness of stimulus needed to evoke a just-perceptible electroretinogram. The electroretinogram threshold is perhaps preferable to measuring larger, super-threshold responses, which may be complicated by complex and changing wave-forms.

GEOPHYSICS

Stress-induced Magnetic Anisotropy of Rocks

$$N = \frac{Q}{\beta - \frac{A}{n} \sin^2 I} \quad (6)$$

or, when I is small :

$$N \simeq \frac{Q}{\beta} \left[1 + \frac{A}{\beta n} I^2 \right] \quad (7)$$

Now, Q is practically independent of solar zenith angle at heights well above the peak for electron production, and this condition is fulfilled above 260 km. according to Ratcliffe *et al.* It follows that the variation of N with I is approximately parabolic, with a minimum at the dip equator. Croom, Robbins and Thomas⁴ have published curves of N against I at various heights obtained from a reduction of ionograms. Their Fig. 1 clearly shows this feature.

The slope of the N/I curve, from equation 7, is given by :

$$\frac{\partial N}{\partial I} = \frac{2QA}{\beta^2 n} I \quad (8)$$

Since $\beta^2 n$ decreases with height more rapidly than Q , the slopes of the N/I curves are expected to increase with height. This feature, also, is shown in Fig. 1 of Croom *et al.* Data from any pair of heights can be used to eliminate the constant A , which is not, at present, well established. At a dip angle of 25° , the curves of Croom *et al.* can then be used to evaluate the scale height for β if the scale heights for Q and n are taken to be roughly equal. For the pairs of curves at 300 and 320, as well as 320 and 340 km., consistent values of about 50 km. are obtained, in good agreement with the value given in Ratcliffe *et al.*

Since it is clear that N must always be positive, an examination of the denominator of equation 6 indicates that the theory presented here may be expected to break down at greater heights and larger values of dip angle. The fact that N/h profiles cease to be exponential away from the dip equator may be considered as one aspect of this theory, which suggests, indeed, that diffusion prevents them from retaining an exponential shape there. Equation 6 also indicates that, at greater heights, this breakdown must occur at smaller values of I . This is evidenced in Fig. 1 of Croom *et al.* by a shift towards the dip equator of the maxima of the N/I curves with increasing height.

It is concluded that quite simple considerations of vertical diffusion account for the major features of the 'geomagnetic anomaly' as presented by Croom *et al.*, and that this anomaly consists of excess ionization, due to diffusion, away from the equator, rather than a deficiency of ionization at the equator.

The work reported here has been sponsored by the U.S.A. National Committee for the International Geophysical Year under Project No. 6.9.

E. R. SCHMERLING

Ionosphere Research Laboratory,
The Pennsylvania State University,
University Park,
Pennsylvania.

¹ Ferraro, V. C. A., *Terr. Mag. and Atmo. Elect.*, 50, 215 (1945).

² Martyn, D. F., *Phys. Soc. Report on Cambridge Ionosphere Conference*, 254 (1955).

³ Ratcliffe, J. A., Schmerling, E. R., Setty, C. S., and Thomas, J. O., *Phil. Trans. Roy. Soc., A*, 248, 621 (1956).

⁴ Croom, Sheila, Robbins, Audrey, and Thomas, J. O., *Nature*, 184, 2008 (1959).

Rocks containing 1 or 2 per cent of magnetic minerals are so slightly ferromagnetic that reliable measurements of magnetostriction by the direct observation of changes in dimensions would, at best, be extremely difficult. However, an understanding of the magnetostriction of rocks is very desirable on account of the disagreement which has arisen concerning its possible role in palaeomagnetism¹⁻⁴. The purpose of this communication is to report an experiment which shows that the saturation magnetostrictions of rocks are easily measured in terms of stress-induced anisotropy, and that, in the few rocks examined, they have values which would be expected from their known magnetic mineral contents.

Five specimens have been used: two samples of Tasmanian dolerite, two of basalt from Kiama, New South Wales, and one of monchiquite, also from Kiama. In all these rocks the natural (unstressed) anisotropies are very small, and, regardless of any slight alignment of grain elongations, the crystallographic axes of the magnetic grains have been shown to be randomly oriented (by the method described by Stacey⁵). In this case the theoretical treatment of magneto-elastic energy, E_s , is simple⁶. When a specimen is subjected to an axial stress (measured as positive for a compression) at an angle θ to a strong field, in which it is magnetically saturated, E_s is given by :

$$E_s = \frac{3}{2} \lambda_s \sigma \cos^2 \theta \quad (1)$$

where λ_s is the saturation magnetostriction. The torque T_s exerted on the specimen by the field exceeds the torque T_0 due to its natural anisotropy by an amount :

$$T_s(\theta) - T_0(\theta) = - \frac{dE_s}{d\theta} = \frac{3}{2} \lambda_s \sigma \sin 2\theta \quad (2)$$

Torque curves $T_s(\theta)$ and $T_0(\theta)$ have been measured for the five specimens.

Each specimen was cut and ground to the shape of a cylinder, 21 mm. in diameter by 15 mm. long, with an axial hole 9.5 mm. in diameter. It was compressed between copper washers, 3 mm. thick, and thin lead washers by tightening a copper nut and bolt which were inserted through the axial hole. The load applied was the same in all cases and was controlled by tightening the copper bolt until it was felt to yield. The load was measured by pairs of electrical resistance strain gauges which were stuck on to two of the specimens, making rock load cells. These cells were calibrated in a mechanical load-testing machine, and the stress applied to the specimens by means of the copper bolt was measured as 520 kgm./cm.² $\pm$ 10 per cent (5.2×10^8 dynes/cm.²).

The specimen plus copper bolt was sufficiently small to be suspended on a simple torque-meter, described previously⁷. First the torque $T_0(\theta)$ exerted on the unstressed specimen (plus copper bolt) by a 10.6 kilo-oersted field was measured as a function of the angle θ between the axis of the bolt and the field direction. The torque curve $T_s(\theta)$ in the stressed state was then measured in the same way, and afterwards the $T_0(\theta)$ curve was repeated to show

The relative breaking stresses measured by me with different liquids agree well with those obtained by Culf³, who measured the extension of cone cracks in glass under different liquids. They can best be explained by a mechanism involving a lowering of the interfacial free energy γ , which according to Griffith's

formula $\sigma \approx \sqrt{\frac{E \cdot \gamma}{c}}$ leads to a reduction of the

tensile stress σ necessary to propagate a crack of length c in a solid having Young's modulus E . Available data on free energies of immersion⁴ indicate that $\gamma_{SO} - \gamma_{SL}$ is largest for water, intermediate for polar organic compounds, and lowest for nonpolar compounds, where γ_{SO} is the free energy of the solid surface in a vacuum and γ_{SL} is the free energy of the solid-liquid interface. The relative order of magnitude of the free energies of immersion agrees well with the order of breaking strengths obtained with different liquids (Table 1). If the strength impairment of glass were exclusively a chemical solution process, the effect of oleylamine, in which quartz is virtually insoluble, on the breaking strength could not be explained. Charles⁵ has pointed out the close correspondence between the concepts of failure by stress corrosion and by lowering of surface energy, which are both compatible with the Griffith criterion. By measuring crack propagation in polar systems that are non-solvents for the solids under consideration, the mechanisms can be separated.

RADIOPHYSICS

Effects of Vertical Diffusion of Electrons near the Magnetic Equator

If electrodynamic movements are neglected, the continuity equation for the electron density N at a fixed height h in region F of the ionosphere may be written:

$$\frac{\partial N}{\partial t} = Q - \beta N + D \quad (1)$$

where Q is the rate of production of electrons, βN is the effective rate of loss due to recombination processes and D is the contribution due to diffusion. If diffusion is considered to be predominantly vertical, the expression of Ferraro¹ reduces to the following form:

$$D = \frac{b}{n} \sin^2 I \left[\frac{\partial^2 N}{\partial h^2} + \frac{3}{2H} \frac{\partial N}{\partial h} + \frac{N}{2H^2} \right] \quad (2)$$

where b is a constant, I is the dip angle of the Earth's magnetic field, n is the density of neutral particles, and H is the scale height, here assumed constant. It is also assumed that H is the same for the neutral

Fig. 1. Mean noon N/h profiles

atmosphere as for the ions: if this is not true, the conclusions reached here will remain essentially unchanged, but the values of the constants will be modified.

The effects of diffusion on a parabolic layer have been investigated by a number of authors; among them Martyn² and Ratcliffe, Schmerling, Setty and Thomas³. Their conclusions cannot be presented in any simple form, since both the magnitude and sign of the diffusion term depend drastically on the ratio of the parabolic thickness to the scale height.

In the vicinity of the magnetic equator, it is found that the electron density/height profiles are closely exponential in shape below the F_2 peak during the day. This is illustrated in Fig. 1, where monthly-mean noon profiles are shown for the three stations Huancayo (Peru), Talara (Peru) and Panama (Canal Zone) for summer, equinox and winter months in 1958. A logarithmic scale has been used for N , and it is seen that the profiles are closely exponential at Huancayo (dip 1°) and Talara (dip 13°) for a range of height of 260–400 km. Even at Panama (dip 38.5°), the deviations from this shape are small in the range 260–360 km. It must be noted that, at Panama, there is some distortion in the mean profiles due to large day-to-day variations of height; profiles for individual days are frequently even closer to exponential form below 360 km.

Representing the profiles by:

$$N = N_0 \exp kh \quad (3)$$

where N_0 and k are constants, we obtain:

$$D = \frac{b}{n} \sin^2 I \left[k^2 + \frac{3}{2} \frac{k}{H} + \frac{1}{2H^2} \right] \quad (4)$$

It is immediately seen that D is always positive and proportional to N . The effect of diffusion is, therefore, always to increase the electron density (below the electron peak). Equation 1 may then be written:

$$\frac{\partial N}{\partial t} = Q - N \left[\beta - \frac{A}{n} \sin^2 I \right] \quad (5)$$

where A is a constant, simply related to b , k and H .

A few simple deductions follow immediately from equation 5. Assuming quasi-equilibrium near noon for heights below 360 km.:

180	548	59

Table 2. OVER-VOLTAGE (FIXED) ON THE SOURCE COUNTER, 180 V.

Over-voltage on the second counter (V.)	Coincidences per 10 min. without filter	Coincidences per 10 min. with filter
20	13	Nil
60	459	5
100	567	8
140	540	46
180	532	51
220	541	62

set the voltage on the source counter was fixed and that on the second counter was changed within its plateau, keeping the channel directed towards its cathode at a fixed angle.

Observations were taken with different distances between the counters. Typical results are given in Tables 1 and 2.

The increase in the number of coincidences in Table 1 with the over-voltage on the source counter is due to greater yield of ultra-violet photons from it with rise in its operating voltage. The increase in the coincidences with the over-voltage on the second counter with filter in Table 2 is, we believe, due to its greater photoelectric efficiency with the rise in the electric field on its counter cathode. The change in the photoelectric efficiency with the electric field on the counter cathode may be due to the 'return' to the cathode of photo-electrons released from it by photons; a phenomenon which has scarcely been studied so far in self-quenching Geiger-Müller counters.

A comparison of the results in Table 2 with filter and without it indicates that the coincidences without filter are mainly due to the photoelectric effect of photons of the source counter falling on the cathode of the second and that photons other than those of wave-length 2537 Å. must be present to account for their greater number. We believe, however, that the hard component of the ultra-violet photons is also causing coincidences by ionization. That photo-ionization is also occurring has been checked by firing the photon beam axially across the second counter and noting the coincidences with and without filter. In the former case there was not a single coincidence in 10 min., whereas in the latter 100–200 coincidences were obtained in the same interval of time.

In other experiments we have shown that ultra-violet photons of long wave-length can travel across a tube 10 cm. long, filled with alcohol at a pressure of 1–3 cm. mercury or even higher. These photons were detected at the end of their journey by a self-quenching Geiger-Müller counter due to their photoelectric effect on its cathode. The ultra-violet radiation was produced by a mercury arc with a quartz window on a side tube. These results are in agreement with our work with counters.

Our results may be of interest also in connexion with the preparation of self-quenching Geiger-Müller counters with a filling of permanent gases⁴.

We are grateful for the supply in 1959 under the Colombo Plan of electronic equipment, some of which was used in this work.

Impairment of Strength of Quartz Glass through Wetting by Liquids

In a recent communication¹, Radd and Oertle attributed the impairment of the tensile strength of glass fibre fabrics to a chemical solution process. Recently I have measured the tensile strength of quartz-glass rods immersed in various liquids. The rods, which were supplied by the Amersil Quartz Division of Engelhardt Industries, Inc., were selected for a uniform diameter of 1 mm. and cut to a length of 10 cm. They were annealed to remove residual strains. Three-point bending, using a calibrated spring, was used to apply a maximum stress at the centre, where the rods were scratched before they were broken. Scratches of identical depth were made on the underside of each rod by cutting with a diamond cutting tool that was applied with a constant force. All experiments were performed in a moisture-free atmosphere on previously dried rods. The mean loads at fracture, together with the 95 per cent confidence interval for the liquids water, oleylamine, and *n*-hexadecane, are shown in Table 1. Great care was taken to free the *n*-hexadecane of all polar impurities and the oleylamine of water. The last column shows the probability of the null hypothesis $M_1 - M_2 = 0$ being correct for the means of the two pairs water-oleylamine and oleylamine-*n*-hexadecane, respectively².

Table 1

Environment	Mean fracture load (gm.)	Probability of null hypothesis $M_1 - M_2 = 0$
Distilled water	18.3 ± 2.1	0.001 < P < 0.005
Oleylamine	18.8 ± 3.0	0.01 < P < 0.025
<i>n</i> -Hexadecane	24.5 ± 3.8	

In another experiment I measured the time that elapsed before delayed fracture set in when seven quartz-glass rods were immersed in *n*-hexadecane and seven were immersed in oleylamine, all of which were then subjected to the same load, which corresponded to 95 per cent of the mean rapid fracture load measured with oleylamine. The breaking times until fracture are listed in Table 2.

The breaking stress-time relationship apparently results from the gradual penetration into the crack of substances that are adsorbed on the crack wall and lower the interfacial free energy.

Table 2

Environment	Time until fracture (sec.)
<i>n</i> -Hexadecane	1,326; 2,886; 16,560; 480; 2,127; 11,775; 990
Oleylamine	15; 0; 55; 10; 6; 0; 2

Fig. 1. Electrical conductivity (d.c.) of strontium oxide as a function of applied voltage over the temperature-range 823–1182° K.

above 1013° K. over the whole range of applied voltage. This is interesting in itself.

Some confirmation of this interpretation comes from the results with alternating currents (5 kc./s.); there was no fall in conductivity with field and no plateau at 1013° K. Contact with oxygen at 10^{-3} mm. mercury pressure of the well-activated strontium oxide surface scarcely affected the a.c. conductivity, which still showed the same features of temperature and field; this was much enhanced on contact with hydrogen. The results so far show that oxidation and reduction treatments produce a desirable quality—a conditioning towards a homogeneous oxide.

Soft Ultra-violet Photons in Self-quenching Geiger-Müller Counters

THOUGH it is now certain that, in a self-quenching Geiger-Müller counter filled with a conventional argon-alcohol mixture, both photo-ionization¹ and photo-emission² cause the spread of the discharge along its anode, the production of ultra-violet photons which are responsible for these two processes and their relative importance in determining the counter characteristics have not yet been fully understood. Further, no reliable data are available for the energy spectrum of these photons, which may be emitted by any of the following mechanisms: (1) de-excitation of excited argon atoms formed in Townsend avalanches giving rise to wave-lengths

in the energy-range 11.5–15.7 eV.; (2) charge-exchange between argon ions and alcohol molecules, producing monochromatic photons of energy $(I_1 - I_2)$ eV. corresponding to a wave-length of about 2800 Å., I_1 and I_2 being the ionization potentials of argon and alcohol respectively; (3) recombination of argon ions with electrons in the vicinity of the anode to the excited levels of argon atoms.

Soft ultra-violet photons which may liberate secondary electrons from the cathode will arise from (2) and (3). There will be no soft ultra-violet photons, other than those of wave-length 2800 Å., if process (3) did not occur within the time-interval of a major pulse, namely, about a microsecond.

Some workers³ believe that soft photons do not play any important part in the spread of the discharge. We have shown that this is not so. The present work has led us to the following conclusions: (i) soft ultra-violet photons energetic enough to liberate photo electrons from the counter cathode are produced in the counter due to recombination of argon ions; (ii) ultra-violet photons have a much smaller absorption coefficient in alcohol than is usually assumed; (iii) the photoelectric efficiency of a self-quenching counter is dependent on its over-voltage, a point of considerable interest in the operation of these tubes.

Two brass counters, each 5.5 cm. in active length and 4.3 cm. in diameter, with tungsten anodes 0.2 mm. thick are housed in a specially constructed steel chamber 12 in. in diameter and 9 in. deep. They are supported in position within the chamber with two Wilson seals passing through its steel bottom plate. A second steel plate with a central window 9 cm. in diameter and covered with a polystyrene disk closes the top of the chamber. The two steel plates are screwed together with steel rods and the chamber is made air-tight with 'O' rings pressed between its wall and the two end-plates, while the polystyrene disk is fixed with 'Araldite'. A third Wilson seal also passing through the bottom steel plate carries within the chamber a framework which holds a narrow-band ultra-violet interference filter which was inserted in between the two counters when desired. The filter, type U 417, supplied by Messrs. Barr and Stroud, Ltd., of Glasgow, has peak transmission at 2537 Å. and has a band-width (half-peak to half-peak) of 160 Å.

One counter acts as a source of photons and is irradiated by a collimated gamma-ray beam to give a counting rate of about 2,000 c./m. while the other counts 300–400 c./m. The end facing the second counter is closed by an insulating cap carrying a narrow channel 2 cm. long at its centre. The two counters had their anodes on a common axis when facing each other and were adjusted by means of the Wilson seals. The chamber was filled with an argon-alcohol mixture containing 10 per cent alcohol at a total pressure of 10 cm. of mercury.

The pulses from the counters were fed into a coincidence unit, type 1036 B, with a resolving time of 1 μsec. and the coincidence pulses were recorded in the scaler, type 200 A. The counter voltages were supplied from stabilized power units.

Coincidences were observed with the channel of the source counter directed towards different parts of the second counter with and without the ultra-violet filter between them.

In one set of experiments the over-voltage of the source counter was changed, keeping that on the second counter fixed in its plateau range. In another

of the film to rotate abruptly into the equivalent antiparallel directions, thus forming more or less oppositely directed domains bounded by walls of something less than 180° . At the higher values of H_L , rotation within these domains occurs. The local deviations of the direction of anisotropy account for the rotational hysteresis. This idea is supported by the experimentally observed fact that those films which have less hysteresis for $h_L > 1$ obey equation 3 to larger values of H_L ($h_L < 1$).

Fig. 1b suggests the use of equation 3 to determine H_K . To within the accuracy with which y_0 represents ΔR_0 , equation (3) can be written as $y/y_0 = (x\bar{D}_z/H_K)^2$, where $\bar{D}_z$ is the horizontal scale factor in oe./cm. Photographic enlargements of the oscilloscope traces are projected on to graph paper from which x , y , and y_0 are measured. The slope of the linear portion of a plot of y against x^2 is used to calculate H_K . Fig. 2 shows such plots for the traces of Figs. 1b, c and d. That for Fig. 1d corresponds to one lobe of the hysteresis curve. The initial slopes yield values of H_K in agreement with the extrapolated linear portions of the magnetic hysteresis curves in Fig. 1a. Table 1 lists the values of H_K obtained by the two methods for four films. These values are in agreement to within the accuracy of the magnetic method. It is perhaps significant that H_K as measured by either method is dependent on the amplitude of the sinusoidal magnetizing field.

Fig. 2

For film studies there are some advantages in the magnetoresistive method. The proportionality of the signal to the square of the cosine of the angle between current and magnetization and the independence of the signal on rate of magnetization make it possible to distinguish experimentally between domain rotation and 180° -wall motion. Furthermore, the independence of rate makes observation of the magnetization process at low magnetizing frequencies particularly easy. Compare the signal-levels obtained from the two methods at 500 c./s. and 20 c./s. (Fig. 1). The direct current in this case was 30 m.amp.; however, it is limited only by the maximum safe current density. For this particular film, currents as high as 300 m.amp. have been applied with no apparent ill effects. The large ratio of surface to volume of a film is favourable for the dissipation of Joule heating. Finally, the simplicity of the magnetoresistive method makes it particularly useful for remote measurements; for example, in a cryostat, or *in vacuo*.

The samples were prepared in this laboratory by R. E. Wimberly, J. W. Chambers and L. J. Boudreaux.

Electrical Conductivity of Strontium Oxide

THE part which strontium oxide plays in the functioning of the oxide cathode is not well understood; a suitable model of the combined barium and strontium oxides on the band theory is still not satisfactory. Further, lack of sufficient observations in the soft X-ray region over the operating temperature-range prevents a fuller knowledge of how the valence band densities are related in the solid solution of the oxides. It is, of course, possible to go some way towards understanding the oxide cathode if the main and relevant properties of each component can be studied.

With this in view, we have concentrated attention on the electrical properties of strontium oxide and find, using a double platinum 'probes' technique, that the electrical conductivity (d.c.) varies with the applied voltage over the temperature-range (823–1182° K.) in the manner shown in Fig. 1. The voltage between the probes has been plotted rather than the field, since the latter is bound to be 'patchy' owing to the presence of a non-uniform porous dielectric.

It is remarkable that, in contrast to the behaviour of barium oxide, the electrical conductivity varies with the field; there appear to be two transitions involved—one due to the field, the other due to temperature. A 'knee' is seen to develop at an applied voltage of about 20 V., and the conductivity is sensitive to the effects of the field only below this, or above 1013° K. Why, at this particular temperature and field, strontium oxide behaves according to classical theory (with the usual assumptions) is not clear; the fall in conductivity with field at the lower temperatures is curious, and might be attributed to electrostatic effects, accompanying changes in current density, between irregular crystallites which affect and alter the contact resistance between them.

The change of slope from negative to positive at the knee voltage around 1013° K. indicates a predominating effect due purely to thermionic emission; indeed, this could explain the rise of conductivity with field wherever it is observed on the curves. A rough estimate of the effect shows that the Langmuir-Child space charge law has a maximum index of about 1.3, and could be fitted to each set of results

PHYSICS

Magnetoresistive Measurements on Domain Rotation in Nickel-Iron Alloy Films

FOR low saturating magnetic fields, the magnetoresistive effect in a polycrystalline ferromagnet is described by the relation¹:

$$\Delta R = \Delta R_0 \cos^2 \varphi \quad (1)$$

where ΔR_0 is the positive resistance change measured when the electric current i is oriented first normal then parallel to the saturation magnetization M_s ; and φ is the angle between the current and the induction. This relation has been verified for evaporated nickel films by Rappeneau².

A film which has uniaxial anisotropy energy E is described by the relation $E = K \sin^2 \theta$, where θ is the angle between M_s and the direction of minimum anisotropy energy, called the K -axis. If such a film is magnetized by a field H_1 in the film plane normal to the K -axis, the equilibrium angle θ for any field less than, or equal to, $H_K = 2K/M_s$ is given by:

$$\sin \theta = h_1, \quad h_1 = H_1/H_K \quad (2)$$

provided that the magnetization rotates uniformly in the plane of the film^{3,4}. If the current is normal to the K -axis, substitution of $\sin^2 \theta$ for $\cos^2 \varphi$ in equation (1) yields:

$$\Delta R/\Delta R_0 = h_1^2 \quad (3)$$

If the current is parallel to the K -axis, the result is $\Delta R/\Delta R_0 = 1 - h_1^2$. Thus, a plot of $\Delta R/\Delta R_0$ against h_1 should be a parabola over that range of h_1 for which equation (2) is valid in a given film.

Fig. 1a shows the magnetic hysteresis curves for a field-evaporated 80-20 nickel-iron film, 2000 Å. thick, magnetized by a sinusoidal field of 500 c./s. of amplitude $\hat{H}_1$ normal to the K -axis. The closed loop at low field demonstrates the applicability of equation (2), see refs. 3, 4. The value of field at which this curve is extrapolated to saturation is usually taken as a measure of H_K . Figs. 1b, c and d are the magnetoresistive hysteresis curves taken for those values of $\hat{H}_1$ in Fig. 1a. The measuring circuit used to obtain the latter is described by Hellenthal⁵; namely, a sinusoidal magnetizing field (20 c./s.) produces, as a result of the magnetoresistive effect, an alternating voltage across a film through which a constant direct current (30 m.amp.) is passing. The voltage is amplified and displayed on the vertical plates of an oscilloscope. The magnitude y of the vertical display is proportional to ΔR , while the horizontal display x is proportional to H_1 . The voltage to produce x comes from the voltage drop across a resistance in series with the magnetizing coils. In the present experiment, the films are rectangular (5 mm. $\times$ 20 mm.) and deposited on soft glass.

For these experimental conditions the magnetoresistive curve for $\hat{H}_1$ sufficiently small should be a parabola described by equation (3). Fig. 1b shows that such is indeed the case. Figs. 1c and d show

Fig. 1

that as $\hat{H}_1$ is increased the parabola opens up, and hysteresis occurs. Fig. 1d, for $h_1 > 1$, is especially significant. The maximum change of d.c. resistance ΔR_0 for this film was found to be 0.060 ohm by potentiometric measurements in a static magnetic field. This value agrees with that calculated from the maximum change y_0 in Fig. 1d to within the accuracy of both measurements (± 5 per cent). This result has been verified for all the films which have been studied (Table 1), and it indicates that the process of magnetization when H_1 is applied is predominantly one of domain rotation accompanied by rotational hysteresis.

These observations, together with those of Bradley and Prutton^{6,7}, suggest the following description of the transverse magnetization process in nickel-iron alloy films having uniaxial anisotropy. When the film has been previously saturated along the K -axis and H_1 is sufficiently small, the process is one of uniform reversible rotation of the magnetization within the plane of the film. However, with increasing H_1 , the local deviations of the direction of anisotropy within the film as proposed by Harte⁸, together with the demagnetizing field of the film relative to the average K -axis, make it favourable for some regions

Fig. 6. X , observed values. The numbers 1-12 indicate sampling months, 1959

ponents, both of which have approximately the same shape. These results are consistent with the observations reported by Ambrosen⁵ on activity in precipitation and by Peirson *et al.*⁶ on tropospheric activity, that about 50 per cent of the long-lived activity, sampled in the first six months of 1959, emanated from October 1958.

By a similar analysis of the results during May-July 1958 (Fig. 7) it is found that at most 30 per cent of the caesium-137 emanates from February 1958, and a large part of the remainder comes from 1957. During the autumn of 1958, the caesium-137 level is fairly constant and high compared with the same period in 1959. A possible reason for this is the February 1958 tests, if it is assumed that these tests gave a contribution of the same type as the October 1958 tests with a maximum about six months after the tests.

Fig. 7. X , observed values. The numbers 5-7 indicate sampling months, 1958

The additional information that can be obtained from the antimony-125 values is rather limited because of the large variation in yield with fission mode for this mass-chain (cf. Table 2). The antimony-125/caesium-137 ratio is given in Fig. 5. It is seen that the values for the period April-September 1958 are fairly constant, and have a mean value of 0.37, whereas the period April-July 1959 has a mean value of 0.52. If it is assumed that the antimony-125 yields are the same for the different injections, this increase corresponds to a decrease in age of about one year; that is, that the mean age of the debris at the time of sampling was the same. The rather large variations for September 1957-March 1958 and October 1958-January 1959 might be due to experi-

mental errors in the determination of antimony-125, as the samples from these periods were very weak.

The main feature of the observations reported in this article and elsewhere⁷ is a pronounced seasonal variation of the caesium-137 content in ground-level air during 1958 and 1959. This, however, does not necessarily imply a seasonal variation in the transport properties of the upper atmosphere, as the major injections of debris in high northern latitudes took place in the autumns of 1957 and 1958, and the variations thus may be explained by assuming a mean residence time in the stratosphere of about six months for such debris, independent of the time of injection. Only when the contributions from the preceding autumn have been subtracted from the total content is it possible to get a fairly unequivocal indication of a 'true' seasonal variation. As is found, a pronounced variation of this type seems to exist during 1959 and there are indications of it during 1958. These observations are thus in concordance with the model of stratospheric fall-out presented by Stewart⁸ and Machta⁹.

However, it has not been verified that this type of variation applies to injections at high latitudes. As is pointed out by Martell¹⁰, there are indications that the mechanism of stratospheric fall-out from such injections differs in such a way that the residence time is considerably shorter (~ 6 months) than for injections at low latitudes, and not very dependent on the time of the year. The results presented here do not contradict this theory. On the contrary, some features seem to support it, for example, the relatively high caesium-137 values during the autumn of 1958 which may be due to the February 1958 tests.

Fig. 4

ratios is given for mixtures where one component originates from October 1958 and the remainder is from June 1958 or earlier. The ratios refer to October 18, 1959. The K -values are the fraction of caesium-137 originating from October 1958. A binary mixture is given by a straight line in the diagram between the points representing the pure components. A point on this line defines a K -value. If this value is kept constant and the origin of the older component is varied from very old (that is, zirconium-95/caesium-137 and cerium 144/caesium-137 ≈ 0) to June 1958, an arc is obtained (for example, $ABCD$). All mixtures of two or more components with a given K -value will be represented by points in the area obtained by connecting the ends of this arc by a straight line.

By inserting observed values in Fig. 6, some indication of the mixing-ratios and the age of the older components can be obtained.

For an evaluation of the uncertainty in this estimation, it is necessary to consider both the errors in the experimental and the theoretical values. The former are partly statistical and partly systematic, due to difficulties in the interpretation of the γ -spectra. The latter are systematic and are a result of uncertainties in yield values and half-lives, as well as fractionation. From a practical point of view, it is advantageous to attribute all these errors to the experimental points and regard the theoretical values as fixed. An indication of the magnitude of the statistical errors is given by the measurements from the period January–June 1959, during which no systematic variation in the observed ratios could be seen. From an analysis of these values, it is found

that the standard deviations are 6 per cent for the ratios zirconium-95/caesium-137 and cerium-144/caesium-137, and 3 per cent for the zirconium-95/cerium-144. The systematic errors from uncertainties in yield values and half-lives can be roughly estimated to 15–20 per cent. As an estimate of the total maximal errors, the following values have been chosen: zirconium-95/cerium-144, 20 per cent; cerium-144/caesium-137, 25 per cent; and zirconium-95/caesium-137, 25 per cent.

In Fig. 6 an experimental point corresponding to the mean values for the sampling period January–June 1959 has been inserted. Adding the errors as assumed above, a hexagonal area as indicated in the figure is obtained. As this area is rather large, no very accurate conclusions about mixing ratios can be made. However, it can be seen that between 20 and 55 per cent of the caesium-137 originates from October 1958, and that a large part of the older component emanates from September 1957 or later. The experimental points for the second half of 1959 indicate an increased mixing ratio of older components with time, and the mean age of these older components also seems to increase with time. This trend can be considered significant, as the greater part of the assumed errors is systematic and to a large extent common for all points.

From the possible mixing ratios for samples from 1959, estimated as above, it is concluded that between 50 and 100 per cent of the zirconium-95 in these samples can be attributed to the October 1958 tests. The activity of zirconium-95 plotted in Fig. 2 thus gives, as regards 1959, a fairly good picture of the time-variation of the activity of this origin (corrected for radioactive decay). The maximum occurs about 6 months after the tests, and has a half-width of 5–6 months. The peak value corresponds to $(1-2) \times 10^7$ fissions per kgm. air. One year after the tests the level is only a few per cent of the maximum value.

Only 55 per cent of the caesium-137 peak in the spring 1959, given in Fig. 1, can originate from October 1958, as concluded from Fig. 6. If this contribution is subtracted from the total caesium-137 activity, a pronounced peak still remains. It thus seems that the peak in 1959 consists of two com-

Fig. 5

Table 3. HIGH-YIELD EXPLOSIONS ON THE NORTHERN HEMISPHERE 1957–58

Test period	Country	Explosion date used in the calculations
April 8–16, 1957	U.S.S.R.	April 10, 1957
Aug. 22–Oct. 6, 1957	U.S.S.R.	Sept. 15, 1957
Feb. 23–27, 1958	U.S.S.R.	Feb. 25, 1958
June 28, 1958	U.S.A.	June 28, 1958

Fig. 2

caesium-137 and cerium-144/caesium-137 ratios with calculated values. The calculation of these ratios implies large uncertainties as the type of fission (fissionable material, neutron energy-spectrum) can only be roughly estimated, and furthermore, the yield-values are quite uncertain in many cases. In Table 2 yield values for the possible fission modes are given*. Mean values of the yields for fast and

Table 2. YIELD VALUES (PER CNT)

Mass chain	Type of fission

144	4.75	4.55	3.62	3.24	3.23

14-MeV. fission of uranium-238 have been used for the calculations.

A source of error is also introduced by fractionation phenomena*. For example, it has been found experimentally that the mass-chain 95 is enriched in larger particles, which can be explained from the chemical properties of the fission products during the period of particle formation. To estimate the influence of this on the ratios studied it is necessary to have some knowledge of the particle spectrum. Such work is under way at this laboratory. Although the quantitative evaluation of the particle spectra is not yet concluded, it is possible to say that the contribution of larger particles with appreciable fractionation to the total activity is small for debris older than about three months. For this reason we assume in the following that, except for debris with components younger than a few months, the error due to fractionation is small compared with errors in the measurements and theoretical calculations.

In Figs. 3 and 4 the calculated ratios for the publicly known high-yield explosions on the northern hemisphere since 1957 have been indicated (cf. Table 3). It is observed that the experimental zirconium-95/caesium-137 ratio for the first six months of 1959 is nearly constant, and about 0.6 times the theoretical ratio for debris from October 1958, thus indicating an admixture of older debris.

In Fig. 6 the theoretical relationship between the zirconium-95/caesium-137 and cerium-144/caesium-137

Fig. 3

CONCENTRATION OF SOME FISSION PRODUCT NUCLIDES IN GROUND-LEVEL AIR

By K. EDVARSON and KERSTIN LÖW

Research Institute of National Defence, Department 4, Stockholm 80

IN ground-level air the fission product activity originating from nuclear weapon tests varies considerably with time, both in intensity and composition. In order to map these variations, especially regarding the long-lived components, γ -spectrometric measurements have been made on monthly samples of ground-level air taken near Stockholm, Sweden. An attempt has been made to correlate the activity variations with known nuclear weapon tests.

The sampling apparatus consisted of a commercial centrifugal blower (Stephan-Werke, Hameln/Weser, West Germany), to which a filter holder (area 18×18 cm.²) was attached on the inlet side. The filter medium was glass-fibre paper with a thickness of 55–60 gm./m.². The filtering capacity was about 4 kgm. air per min.

The samplers were run continuously, and the filters changed every 24 hr. Thus, each sample contained the particulate activity from about 5,000 kgm. air.

The samples were allowed to stand for 3 days in order to let the short-lived radium and thorium daughter products decay. After that, one quarter of the sample was measured for total γ -activity with a scintillation counter. (The remainder was used for autoradiographic and other investigations.) When the measured samples were strong enough (> 2 no.), individual nuclides were determined by γ -spectrometry. These measurements of daily samples are reported elsewhere^{1,2}. The samples were then pooled to give monthly, or sometimes half-monthly, samples. The γ -spectra of these pooled samples (each corresponding to $1-4 \times 10^4$ kgm. air) were measured with a spectrometer consisting of a 10 cm. $\times$ 10 cm. sodium iodide(Tl)-crystal connected to a 70-channel kick-sorter.

The results given in this article cover the period September 1957–December 1959 for a sampling station near Stockholm (59.2° N., 18.1° E.). The measurements were mainly performed at the end of 1959 and beginning of 1960, and the concentrations of zirconium-95, antimony-125, caesium-137 and cerium-144 were determined. The results are given in Table 1, where all activities have been recalculated to October 18, 1959. For the period May 1958–September 1958 the zirconium-95 values were obtained from measurements made in June 1959. For older pooled samples zirconium-95 values are lacking. Contributions to the γ -spectra were also observed from ruthenium-103 + 106. The relative amounts of ruthenium-103 and -106 could not be determined as their main γ -lines are quite close in energy. An indication of manganese-54 was also observed in most of the samples. In samples from the second half of 1959, which were measured a few months after sampling, beryllium-7 (54 d) was also detected. In these samples it has not yet been possible to determine the antimony-125 content, because the γ -line of this nuclide is masked by the one from beryllium-7.

In Fig. 1 the time-variation of the concentration of caesium-137 is plotted. The main features are two

broad peaks with half-widths of 4–6 months and maxima in June 1958 and May 1959, respectively. A temporary increase is observed in October 1957. From earlier measurements on daily samples, it has been found that about 75 per cent of the caesium-137 activity during this month was collected in one sample (October 13–14). In this sample, considerable amounts of iodine-131, presumably originating from the Windscale accident, were found, and probably most of the caesium-137 has the same source. In Figs. 2, 3, 4 and 5 the values for zirconium-95 and the zirconium-95/caesium-137, cerium-144/caesium-137 and antimony-125/caesium-137 ratios are plotted. The rather sharp increase of the concentration of zirconium-95 at the end of 1958, combined with the increase in the zirconium-95/caesium-137 ratio, is a proof of the appearance of activity of considerably more recent origin. From more detailed age-determinations (for example, from the barium-140/(zirconium + niobium)-95 ratio) made on debris sampled during the end of 1958 and beginning of 1959, it was concluded that this debris originated mainly from October 1958. According to Press data, Russian high-yield tests were performed during October 12–22, 1958.

In the following an attempt is made to calculate the possible dates of origin and mixing ratios of the debris by comparing the measured zirconium-95/

Dec.	13.1.60	1.3		1.5	8.4

The concentration of the measured nuclides have been recalculated to October 18, 1959, using the following half-lives: zirconium-95, 65 days; antimony-125, 2 years; caesium-137, 30 years; cerium-144, 285 days. As no absolute calibration has been made for antimony-125 the absolute values of this nuclide may be in error by ± 30 per cent.

Table 1

<i>Brain Stem Reticular Neurophysiological Characteristics</i>	<i>Behavioural Characteristics</i>	<i>Thalamic Reticular Neurophysiological Characteristics</i>
Tonic reaction	Adaptation Long term Short term	Phasic reaction

Controls sensory input	Blocking Input .. Suppress or aug- ment cortical activity	Suppressive and facilitory action
Intensity generalization	Ability to cope High external with intensity reality testing changes in stimulation	Quality or fine discrimination, continual response to varied stimulus

especially concentration with emotional tone¹⁰. Simultaneous activity of diffuse-specific projection systems can lead to changes in cortical activity, which is dependent on timing of electrical impulses on the thalamic reticular system^{4,10}. Thus it is suggested that sub-cortical blockage of input by stress stimuli delivered at given certain rates would either abolish, increase, or decrease cortical activity (similarly to an artificial stimuli).

Consider now the problem of why performance of the stressed in some cases is organized and in other disorganized (essentially the problem of cognitive motivation). First, studies seem to indicate that the cognitive control mechanism lies in the suppression of reticular activity by the cortex via cortico-thalamic tracts. Integrating the work of Kluver and Bucy, and Forbes and Morrison¹¹, it would seem that the temporal lobe and amygdaloid complex intact could modulate emotions by affecting brain activity through the secondary sensory discharge. With lesions we obtain uninhibited emotional discharge. The cortex controls the activating mechanism of the brain stem reticular system, thereby influencing its own level of arousal. A second mechanism lies in the activity of the brain stem reticular system, which would have to be prepotent with respect to the thalamic reticular system in order to provide a 'cognitive crutch' for the tolerators of stress, while control by the thalamic reticular system of the alpha rhythm¹, by cutting attention, could provide a 'cocoonizing' response to stress. In the latter case we would have a passive response where reality is ignored temporarily, and in the former case an active apprehension, and a longer lasting if not impervious face to stress. While the thalamic reticular system may provide a subsidiary stress control mechanism, it is proposed that the major function is to lead to disorganized responses as supported by Landis's study¹², as well as the isomorphic relations suggested below.

Finally, the question of how stress or emotion can limit disorganization to certain sense modalities (auditory or visual) or disorganize the whole organism is considered. It is known that the thalamic reticular system can localize its activity to one hemisphere, or even one lobe¹⁰, and I have already proposed that the thalamic reticular system is responsible for disorganizing effects. Another secondary mechanism could lie in the key finding¹³ that there is an ordering of the various sensory modes with respect to their effectiveness in inducing cortical activity.

Such rationales for suggesting that the brain stem reticular system and the thalamic reticular system

control organized and disorganized behaviour respectively may be considered too tenuous in the face of what we know of brain-behaviour relationships. Undoubtedly such a picture is tentative, and the following isomorphic relationships (between known neurophysiological reactions and known or deduced psychological data) over-simplified. However, there is also support in that these systems control other variables which are related to the dichotomous effects, namely, that of disorganization-organization².

Additional effects of stress variability due to change and rate of change of stimulation, and the non-linear relationship between increased stress and increased disorganization are discussed with respect to experimentation². Further considered is the influence of individual (especially satiation-level) and cultural factors on disorganization-organization, neurochemical composition of the reticular formation and learning, old-age as a 'natural' sensory deprived group, and the utilization of brain injured and 'quitters' as catalysts for research in concept formation².

This research was supported in part by Contract No. AF41(657-258), from the Arctic Aero-Medical Laboratories, Alaska. Acknowledgment is also made to those who helped in the formulation of the full text (ref. 2).

DISORGANIZATION-ORGANIZATION AND THE RETICULAR FORMATION

By RODABÉ P. BHARUCHA-REID*

Environmental Physiology Laboratory, Department of Physiology,
University of California, Berkeley

WHEN a phenomenon seems to defy elucidation, scientists are often forced to 'look before and after' in the hope that the longer route will prove, in the end, to be the shortest. It is perhaps, therefore, that in seeking an answer to the question: 'What is emotion?' that many workers have studied the subsequent effects of an emotional state. While earlier Darwin and Cannon suggested that emotion gave rise to highly organized response sequences (supported in recent times by Leeper, Duffy, and Webb), others, such as Young, have interpreted emotions as leading to disrupting and disorganizing responses. No satisfactory envisagement of the subject of emotions has been arrived at, and Lindsley¹ has suggested that one reason could be that recent neurological findings have rendered certain prominent theories inadequate.

A critical discussion of theoretical compromises and a major experiment relevant to the Leeper-Young controversy has been presented². It was shown that these compromises by Bindra³ and Hebb⁴, as well as the experimental conclusions of Thompson and Higgins⁵, were untenable on biological, scientific and logical grounds, and in certain cases actually argue for the disorganization point of view.

Therefore a simple alternative solution is suggested, which proposes that any emotion (or stress) may in effect be disorganizing or organizing, depending on whether there is interference from an internal modulating system, namely, cognitive motivation, which can influence and organize brain activity independent of sensory input in the reticular formation^{3,4}; and that emotions are a single sub-class of behaviour to be differentiated from the subsequent effects which may, or may not, be similar to the non-demonstrated effect. The effect of organization would follow from the organism being in such a state of equilibrium with its environment that it may be said to possess the property of adaptability (that is, make for adaption but not necessarily eventuating in it). To ensure that such stability will follow, there is a selection of variables such as not to lead to a critical state (that is, all essential variables lie within their physiological limits). This selection may be automatic as in homeostatic mechanisms (Ashby's principle of ultra-stability), or it may be by the utilization of rational decisions or non-automatic choice as in cognitive motivation. That is, cognitive motivation may be measured by the ratio of maximum use of cognitive control for long-term psychological and physiological survival to a minimum of short-term solutions, overriding all other conflicting needs. By short-term is meant what is temporarily expedient but would not necessarily eventuate, and possibly conflict with survival in the long run; and by psychological survival is simply denoted behavioural equilibrium through a reduction of conflicting responses.

Support for the alternative hypothesis lies not only in experiments which fail to show that stress (or sensory deprivation) necessarily leads to disorganized responses⁵, contrary to the McGill experiments on sensory deprivation, but also in the studies using different species and different emotional, intellectual, social, and audio-visual stresses⁶; demonstrating that stress effects on performance should not be studied independently of the cognitive characteristics of the individual, that stress tolerators do their own reality testing, show organized flexible behaviour with no cognitive disruption, while 'quitters' are unable to maintain rational thought and rely heavily on external reality testing. Such a hypothesis explains both the disorganized and the organized, unlike current theories of sensory deprivation which rely heavily on the deprivation characteristics of the stimulating environment to explain only the disorganized. Studies in other areas⁷ also demonstrate the consistently dichotomous response of the disorganized-organized individuals in varied situations, as well as in respect to neurophysiological variables (that is, disorganized—'quitters', low-satiation threshold, extroverted, poor control primary processes, rigidity, poor cognitive organization, high reality testing, brain injury, thalamic reticular system; organized—'tolerators', high-satiation threshold, introverted, strong control primary processes, flexibility, strong cognitive organization, low reality testing, normals, brain stem reticular system). It is noted² that the satiation phenomenon is centrally involved in these studies and is related to metabolic efficiency (Wertheimer) and the reticular formation⁸, while metabolic activity has been related to stress (Pace).

The usefulness of postulating a neurophysiological model for behaviour has been emphasized by Bertalanffy, Hebb, Krech, and Le Gros Clark, and such an attempt is made with dichotomous effects and the intervening internal modulating system. Adrian and Mathews⁹ state that anaesthetics may produce 'unconsciousness' by suppressing sensory activity so that behaviour is rigid. It is suggested here² that stress essentially replicates the action of pharmaceuticals, thus making stress act as a 'behavioural anaesthetic', and blocking input. Four types of blockage have been discussed in detail². One, differential depressant action, augmenting responses in the non-specific sensory system, by inhibition of the sub-cortical system⁹; second, if sensory input is 'allowed' to be received it is not necessarily elaborated for awareness, depending on inhibition-activation balance sub-cortically⁹; third, cortical stimulation blocks conduction in reticular formation⁴, providing a neurophysiological basis for behaviour involving aberrations under emotional stress; fourth, if the alpha rhythm corresponds to the electrical correlate of external sensory input, then the alpha rhythm is readily blocked by concentration of attention,

* Present address: Department of Biology, University of Oregon, Eugene.

resulted in the manner shown in Fig. 2A. Frequently cracks perpendicular to the surface developed, following which each block of soil acted as a separate unit: during expansion a plane of no movement was found up-slope of the centre of the block, and during contraction a corresponding plane down-slope of the centre, resulting in a net down-slope movement of each block (Fig. 2B). Difficulty was encountered in preventing movement from occurring mainly at the junction of the soil with the base of the trough, but in some cases differential down-slope movement of the upper layer of soil relative to the lower took place.

Creep due to wetting and drying was further reproduced under semi-natural conditions. An undisturbed block of soil $100 \times 20 \times 20$ cm., with overlying turf, was placed in a glass-sided trough, which was tilted to 25° and exposed to natural weather conditions in Sheffield. Movements were recorded monthly for 2 years. Expansion and contraction of the soil corresponded closely with periods of rainfall and drought. The soil acted as a single block, with movement taking place mainly, but not entirely, along the base, at a rate of 5.0 mm./yr. In a second trough filled to 30 cm. depth with disturbed and re-packed soil, the rate of movement decreased regularly from the surface downwards.

These results suggested an indirect means of measuring soil-creep. At three sites on a slope, on the 26° steepest part and at 18° and 7° on the concavity, variations in moisture content of the soil at three depths were obtained by monthly sampling during 2 years. By means of shrinkage tests, the percentage expansion and contraction of the soil for unit change in moisture content at each of these nine points was obtained. Combining these results and interpolating between the sampled depths gave

Fig. 2. Movements in a tilted block of soil subjected to alternate wetting and drying. A, trace of movements during five periods of drying separated by four of wetting; B, diagrammatic representation of movement in a single cohesive block of soil during one cycle of drying and wetting

annual expansion and contraction of the soil on the slope. It was assumed that down-slope movement = $\sin(\text{slope angle}) \times \text{expansion and contraction perpendicular to the ground-surface}$. The results are summarized in Table 1. They show a movement of $0.5-1.0$ mm./yr. close to the ground-surface, and $0.05-0.1$ mm./yr. below 20 cm. depth. The volume of soil movement is $0.8-1.0$ cm.³/cm./yr. The most striking feature is that movement on the 7° -concavity was only slightly less than that of the 26° -slope; this is attributable to the greater fineness of the soil and larger variation in moisture content on the concavity, and probably also to the presence there of expanding-lattice clay minerals.

The rate of the movement of the soil by slope-wash was measured on sites close to those used for soil-creep. Tins were placed in the soil with projecting lips on their up-slope sides (length 30 cm.) inserted just below the boundary of the A_0 horizon and the upper surface of the mineral soil (Fig. 1D). Soil was collected from the tins at 6-18 month intervals during 3 years. The mean of 49 results was 5.1 gm./yr. of soil, equivalent to a down-slope movement of 0.08 cm.³/cm./yr.

The relative ineffectiveness of slope wash is explicable from the presence of an organic cover, the A_0 horizon of grass roots or leaf litter and the A_0 humus horizon. Besides their direct protective effect, these have a large capacity for absorbing moisture during storms, afterwards releasing it slowly to the soil beneath. Samples of the humus horizon taken during storms showed it to be capable of holding moisture contents of $75-90$ per cent by weight, while retaining a firm structure.

These interim results indicate that on the slopes investigated the rate of down-slope soil movement by soil-creep is of the order of ten times as rapid as that by slope-wash.

This work was assisted by a grant from the Research Fund of the University of Sheffield.

Fig. 1. Techniques for field measurement of the rate of soil-creep and slope wash. l_1 , l_2 , l_3 are measured lengths

accelerated soil erosion. This article describes techniques evolved for measurement of the rate of soil-creep under natural conditions, and reports interim results; experiments reproducing this process are described, and the relative effectiveness of soil-creep and slope-wash compared.

In the initial attempt at measuring soil-creep, metal pegs were inserted into the ground surface at short distances downslope of a bedrock outcrop (Fig. 1A). Three marks were engraved on the rock, and distances from each of these to the pegs measured at intervals of time. Down-slope movements are directly obtained by this method, but their interpretation is uncertain; if the surface soil moves more rapidly than that beneath, it will tilt the pegs, exaggerating movements of their upper ends. Measurements during $3\frac{1}{2}$ years indicate that, on grassed slopes of 30° , down-slope movement close to

the ground-surface is of the order of 1 mm. They also show clearly that on slopes steeper than 35° , with a scarred or incomplete turf cover or with terracettes, rate of movement increases rapidly with increase in angle. All results refer to valley slopes in the basin of the Upper Derwent, Southern Pennines, underlain by sandstones with interbedded shales, belonging to the Millstone Grit Series.

To obtain movements of soil in depth, it is necessary to bury markers and afterwards re-excavate, since a vertical soil-face left exposed to the air creates artificial conditions of moisture, temperature and biological activity. Two methods of making such measurements have been employed. In the first (Fig. 1B) a pit was dug through the soil to the rock beneath, and six pegs driven firmly into the rock; when filling the pit, these were protected by covers. A line of metal rods (diameter 2 mm., length 10 cm.) was inserted into one side of the pit, the ends of the rods being flush with the undisturbed soil. Measurements from pegs to rods fixed the positions of the latter in two dimensions. In the second method (Fig. 1C), a vertical line of fine rods, 1-mm. diameter, was inserted flush with the pit side, and their position measured with respect to a plumb-line suspended close to their ends; on re-measurement, the deepest rods, close to bed-rock, were assumed to have remained stationary. This method is of comparatively high accuracy, but gives only the horizontal component of movement. Nine pits were established, and measured on re-excavation at intervals of 6–12 months over 2 years. Disturbances of rods during burial and excavation were distinguishable as random movements, contrasted with systematic movement of adjacent rods due to soil movement. Results indicate that, on grassed and wooded slopes of 20° – 30° , down-slope movement of the upper 10 cm. of soil (excluding the organic horizons) is of the order of 0.25 mm./yr. The unit for measuring volumetric down-slope movement of soil is the volume of soil moved annually across a plane perpendicular to the ground-surface and parallel with the contour of the slope, for unit horizontal distance along the plane, expressed in $\text{cm.}^3/\text{cm.}/\text{yr.}$ The interim results show a movement of the order of $0.6 \text{ cm.}^3/\text{cm.}/\text{yr.}$ They also show that movements in the organic A_0 horizon, both under grass and woodland, were very much greater than in the immediately subjacent mineral soil, amounting to 0.5–2.0 mm./yr. It is hoped to obtain more precise results by re-measuring after the pits have been left undisturbed for 3–5 years.

A list of the causes of soil-creep has been given by Sharpe¹⁰. The majority of these are essentially causes of disturbance in the relative positions of soil particles; down-slope movement is produced by the constant factor of gravity acting on re-adjustments to these positions. Quantitatively, one of the greatest causes of disturbance is the swelling and shrinkage of colloidal components of the soil on wetting and drying. Experiments to reproduce soil-creep by this means have been carried out. Blocks of soil were placed in glass-sided troughs, and pins inserted into the sides of the soil to record movements; the troughs were placed at an angle of 30° , and the soil surface wetted and dried artificially. On wetting, expansion took place perpendicular to the surface; on drying, gravity tends to cause contraction in a vertical direction, but due to cohesion the observed contraction was in a direction intermediate between vertical and perpendicular to the surface. Net down-slope movement

larvæ were washed in water several times and transferred in threes to test-tubes containing a mixture of 1 per cent potassium cyanide with 1 per cent potassium ferricyanide in proportion of 1 to 1.5. The hæm content was then determined by the modified Czezugha method¹.

The results are given on Fig. 1. Each point on the graph was plotted from the average of three measurements. The curve shows that the concentrations of polyvinyl alcohol from 0.001 to 0.1 per cent have a stimulating effect on hæm content. The greatest increase is seen when the solution contained a concentration of 0.005 per cent polyvinyl alcohol. At higher concentrations of polyvinyl alcohol the amount of hæm decreases.

From this experiment and those on increased chlorophyll synthesis, it can be presumed that the same mechanism is operating in both cases. Probably polyvinyl alcohol effects the biosynthesis of the porphyrine parts or makes easier the synthesis of metalloporphyrine.

Increase in Level of Chlorophyll in *Pisum sativum* L.

IN experiments on the effect of polyvinyl alcohol on the development of *Pisum sativum* L., it was found that plants growing in water cultures to which the substance had been added grow more rapidly than control plants¹. Polyvinyl alcohol has a similar effect on the growth of the plant mass. We wished to determine whether this substance has the same effect on the growth of *Pisum sativum* in soil to which it had been added as in the aqueous cultures.

For our experiments pea seeds of the variety 'May' were used. Seventy seeds were planted in boxes each containing hot-bed soil. The boxes were then placed in a room where the average daily temperature varied from 22° C. to 4° C. All the boxes were placed on window sills in the same light.

Four boxes with *Pisum sativum* sowings (group 1) were watered with an aqueous solution of polyvinyl alcohol at a concentration of 0.0001 per cent and four boxes (control, group 2) with water. Seventeen days after the plants had germinated, the shoots above ground were measured (from two boxes in each group). Those parts of the shoots which appeared above ground

were then cut off in order to determine the amount of fresh plant bulk. Chlorophyll was extracted by the T. Godniewa method and its level determined by means of a Lang photocolormeter. The plants in the next four boxes were measured and cut on the twenty-second day of the experiment in exactly the same manner. The level of chlorophyll was calculated in mgm. per 1 gm. of fresh shoot mass above ground.

As a standard, a solution of 8 per cent chlorophyll solution appropriately diluted (R. Marek, Darmstadt) was used. The results are given in Table 1.

Table 1. COMPARISON OF THE RESULTS OF THE EXPERIMENT
Plants growing in soil to which an aqueous solution of polyalcohol vinyl had been added

Box No.	Date of shoot cutting	Average length of plants	Fresh plant mass in gm.	Amount of chlorophyll in mgm. per gm. of fresh plant mass
1	July 10	27.5 cm.	13,500	2.25
2	" 10	26.0 "	14,100	3.55
3	" 14	42.0 "	24,200	3.66
4	" 14	44.0 "	26,500	3.39
Control plants				
5	July 10	22.0 cm.	9,650	1.56
6	" 10	25.5 "	13,400	2.23
7	" 14	34.0 "	9,800	3.32
8	" 14	39.0 "	13,500	2.08

The observations presented in our first report¹ on the intensity of coloration in the parts above ground, which is, in our opinion, directly connected with an increase in chlorophyll content, have been confirmed in this experiment.

In series I, the difference in chlorophyll content between plants growing in polyvinyl alcohol and the controls is considerable—1.01 mgm./1 gm. of fresh mass; in series II this difference is 0.85 mgm./1 gm. of fresh mass. The average for series I and II is 0.93 mgm./1 gm. of fresh shoot mass above ground.

This experiment demonstrates that not only in water solutions but also in soil the growth of plants treated with polyvinyl alcohol is more rapid than the growth of control plants.

SOIL MOVEMENT BY DENUDATIONAL PROCESSES ON SLOPES

By DR. ANTHONY YOUNG

Department of Agriculture, Zomba, Nyasaland

TWO aspects of geomorphology which have recently received increased attention are the rate at which changes in landforms take place, and the study of erosional and denudational processes. Estimates of the rate of landform evolution have been made from indirect geological evidence¹⁻³, or by relating measured river loads⁴⁻⁶ or rates of sedi-

mentation⁷⁻⁹ to the catchment areas from which they are derived. These results combine the material removed in bank and bed erosion with that supplied to the rivers by denudational processes. Direct measurements of the rapidity of denudational processes on hill slopes have related mainly to slope-wash, undertaken in connexion with investigations of

Table 1 CHLOROPHYLL-LEVEL IN *Chlorella pyridinosa* WITH VARIOUS CONCENTRATIONS OF POLYVINYL ALCOHOL

* The average error was calculated from the formula: $Ed^2/n(n-1)$ where Ed is total divergence from average, n is number of measurements.

of chlorophyll was determined by means of a colorimeter on a wave-length of 650 m μ . 10 ml. of the culture were taken at the same time in order to determine the number of cells. The specimens were fixed in formalin and tested 14 days later.

On calculating the average content in each of the specimens tested, it was found that the level of chlorophyll varied according to the concentration of polyvinyl alcohol used (see Table 1). Comparing the results with those for the controls, it is seen that chlorophyll content increases consistently with the increase in the concentration of polyvinyl alcohol. With 0.001 per cent concentration of polyvinyl alcohol, the amount of chlorophyll was doubled, and the optimal solution used in our experiments (0.1 per cent) practically tripled the amount of chlorophyll. In those cases where the concentrations of polyvinyl alcohol exceeded the optimal, inhibition in development of the algae and a marked decrease in chlorophyll-level was observed (see Fig. 1).

Fig. 1. Curve showing the chlorophyll-level in *Chlorella pyridinosa* cultures of various concentrations of polyvinyl alcohols

Fig. 2. Curve showing the dependence of the number of cells is dependent on the concentration of polyvinyl alcohol in the culture

The differences in the number of cells were not so marked as the variation in chlorophyll-level. At the optimal concentrations the number of cells as compared with that of the controls showed an increase of only about 60 per cent. These results are presented in Fig. 2.

Aqueous solutions of polyvinyl alcohol have a marked effect on the chlorophyll-level in algae of the *Chlorella* type. This polymer also affects cells, causing an increase in their number. The rise in the level of chlorophyll in *Chlorella* and the increase in the number of cells are not closely connected and are in the proportion of 3.3 : 1. The significant rise in chlorophyll-level in algae growing in aqueous solutions of polyvinyl alcohol may be due to increased intracellular synthesis.

Hæm Content of Larvæ of *Tendipes* f.l. *plumosus* L.

EXPERIMENTS on the effect of polyvinyl alcohol on the chlorophyll content of algae and other plants showed that this polymer at a concentration of 0.0001 per cent doubles the level of chlorophyll. Since chlorophyll has essentially a similar structure to that of hæm, we decided to investigate whether polyvinyl alcohol has a similar effect so far as hæm is concerned.

The experiments were carried out on *Tendipes* f.l. *plumosus* from the ponds in Dojlidy, Białystok. The larvæ were transported to the laboratory and placed in glass aquaria of 500-ml. capacity. 100 c.c. of silt was put at the bottom of each vessel and 250 ml. of pond water, filtered through triply folded gauze, were poured over the silt. The larvæ were transferred to the aquaria, one larva in each vessel, after which an aqueous solution of polyvinyl alcohol was added so that the final concentrations were: 0.001, 0.005, 0.01, 0.05, and 0.1 per cent. One aquarium was left without polyvinyl alcohol as a control. Meanwhile, 50 larvæ from the same place and collected at the same time as the larvæ used for the experiment were dried at a temperature of 105° C. in a drier in order to calculate the average dry mass of one larva. The hæm content found during the experiment was expressed as the proportion to this average dry mass 14 days later. The

Vitamin A exists in the tissues in several geometric configurations, *cis-trans* isomers of one another²¹. The bleaching and synthesis of rhodopsin involves a cycle of stereo-isomerization: rhodopsin is synthesized from 11-*cis* (neo-*b*) retinene, and on bleaching releases all-*trans* retinene²².

11-*cis* Vitamin A has not been identified in any tissue of the body, except in the eye²³. There Krinsky has found that up to 85 per cent of the vitamin A in the pigment epithelium may be 11-*cis*²³. It is of interest to inquire what isomer of vitamin A is found in the pigment epithelium after prolonged light adaptation. With this in view, the vitamin A was extracted from the pigment layers of six light-adapted animals as described above. The content of 11-*cis* vitamin A was determined by isomerizing with light in the presence of iodine, according to the method of Wald and Brown²⁷. In two such experiments, no 11-*cis* vitamin A was detected.

There is considerable evidence, however, that in some animals the pigment epithelium does isomerize vitamin A^{19,23,28}, and it seems reasonable that vitamin A while in the pigment epithelium of the rat might undergo isomerization. Recently, Hubbard and Colman have shown that the amount of 11-*cis* vitamin A in the eye of the frog remains relatively low during the course of dark adaptation. Then, when the retina has ceased to remove it to form rhodopsin, the amount of 11-*cis* vitamin A in the eye increases 2-3 fold¹⁸. It seemed, therefore, that my failure to detect 11-*cis* vitamin A might be due to insufficient time for detectable quantities of 11-*cis* vitamin A to accumulate. I have tested this thesis in preliminary experiments by incubating the backs of light-adapted rat eyes in phosphate buffer for periods up to 4 hr., but have not as yet been successful in demonstrating the production of 11-*cis* vitamin A.

In summary, most of the vitamin A formed from retinene during light adaptation rapidly moves into the pigment epithelium. After 60 min. of light

adaptation, 75-80 per cent of the total ocular vitamin A is found in the pigment epithelium, mainly as vitamin A ester. During dark adaptation, the vitamin A returns from the pigment epithelium to the retina as rhodopsin is regenerated. In the fully dark-adapted state, the pigment epithelium contains no detectable amount of vitamin A.

This investigation has been supported in part by grants from the National Science Foundation and the U.S. Public Health Service.

I should like to thank Prof. George Wald for many helpful discussions and suggestions.

EFFECT OF POLYVINYL ALCOHOL ON CHLOROPHYLL AND HÆM IN CHLORELLA AND TENDIPES

The Level of Chlorophyll in *Chlorella pyridinosa*

IN experiments on *Pisum sativum* L., it was found that polyvinyl alcohol when applied to soil increased the chlorophyll content of the green parts of the plants (ref. 1, and unpublished work by H.F.N. and L.R.). In order to determine what additional factors contribute to this increase we decided to study the alga *Chlorella pyridinosa* which had been bred directly in an aqueous solution of polyvinyl alcohol. Polyvinyl alcohol produced in Poland (known as 'Salvar', 'Polyviol', 'Alvy', and by other names) was used for these experiments. It was intended to carry out the experiments in aqueous cultures with Pruess medium, on which a rapid growth of *Chlorella* has been observed². However, preliminary experiments showed that one of the elements of that medium, casein, led to errors in measurement. In view of this, cultures from ponds in Białystok were set up in aquaria of 500-ml. capacity. In order to avoid con-

tamination and to remove zooplankton organisms, the culture was filtered by means of a triply folded gauze, after which 400 ml. of the filtrate from the *Chlorella* culture were poured into each aquarium.

The polyvinyl alcohol was prepared as a 10 per cent aqueous solution and different quantities added to the different cultures to give various concentrations of polyvinyl alcohol in them. Concentrations which gave an increase in chlorophyll content were used; they were: 0.00001, 0.0001, 0.001, 0.01, 0.1, 0.5, and 1 per cent. Two aquaria with cultures but no polyvinyl alcohol were used as controls. The experiment lasted 14 days. As early as the tenth day of the experiment, a difference in the intensity of the green colour could be detected with the naked eye. On the fourteenth day of the experiment, 50-ml. specimens were taken from each aquarium and filtered through No. 5 gauzes. The filtered specimens were then dried for three days in a dark room at a temperature of +18° C. Chlorophyll was extracted with ethanol and the content

Fig. 4. Distribution of retinene and vitamin A in the eye during light- and dark-adaptation. During light adaptation, the retinene content of the eye falls, as the retinene, liberated on bleaching of rhodopsin, is reduced to vitamin A. Vitamin A in the retina rises for a time, and then declines, while the bulk of the vitamin A moves into the pigment layers. During dark adaptation, these processes are reversed. The retinene content of the eye increases, as rhodopsin is re-formed, and reciprocally the vitamin A in the pigment layers and retina declines. Dark adaptation is completed in about 100–120 min.

dark adaptation, the animals were placed in a small darkroom. At selected times during light- or dark-adaptation, the animals were anaesthetized with nembutal (15 mgm.), their eyes enucleated, and the retinas and pigment layers dissected apart, and placed separately in small mortars. (Throughout this article I shall refer to the back of the eye (pigment epithelium, choroid and sclera) as the pigment layers, even though there is no pigment in these tissues in the albino rat.) For each measurement, three animals (six eyes) were used.

The tissues were dried by grinding with a small amount of sodium sulphate, and the resulting powder transferred to a test-tube and extracted by vigorous stirring in 3 ml. of chloroform. After centrifugation, the clear chloroform extract (2.2–2.4 ml.) was drawn off, evaporated to dryness, and 0.3 ml. of fresh chloroform added. The amount of vitamin A and retinene in the extracts was determined by the Carr-Price reaction. For this, 0.25 ml. of the chloroform extract was mixed with 0.5 ml. of saturated antimony trichloride solution and the absorption spectrum from 700 to 500 m μ run immediately in the Cary recording spectrophotometer. Retinene absorbs maximally at 664 m μ , and vitamin A absorbs maximally at 620 m μ . When mixed, the amounts of vitamin A and retinene can be calculated by means of simultaneous equations²¹.

Fig. 4 shows the results. It is convenient to express these in terms of the total potential vitamin A content of the eye; that is, vitamin A plus retinene, free and bound.

In completely dark-adapted animals, about 95 per cent of this potential vitamin A is bound as retinene in rhodopsin. About 5 per cent is stored as vitamin A in the retina. No vitamin A is found in the pigment layers.

On exposure to bright light, rhodopsin is bleached, liberating retinene. The retinene content of the retina, however, rapidly falls, as the released retinene is reduced to vitamin A. Reciprocally, the retinal vitamin A increases, and almost immediately vitamin A appears in the pigment layers.

With further time in the light the retinene content of the retina continues to fall, and after 30 min. reaches a level 10–15 per cent of the total potential vitamin A content of the eye. The retinal vitamin A, on the other hand, increases during the first 10 min.

of light adaptation to a maximal level representing about 30 per cent of the total, and then gradually declines. After 45–60 min., it forms plateaux at a level of 10–12 per cent of the total.

The vitamin A in the pigment layers increases throughout the period of light adaptation. After 60 min., 75–80 per cent of the ocular vitamin A is found here. Retinene is never found in the pigment layers; the reduction of retinene to vitamin A takes place solely in the retina, and it is only vitamin A that migrates from the retina into the pigment layers.

It appears from Fig. 4 that there is more vitamin A present in the pigment epithelium after 1 hr. of light adaptation than there is total vitamin A (including retinene) in the eye to begin with. This is probably not the case; this artefact seems caused by my method of extraction, which removes vitamin A more efficiently than retinene. With equal amounts of vitamin A and retinene in a tissue, I extract only about 85 per cent as much retinene as vitamin A. This discrepancy could readily be corrected in the figure, but the raw data as they stand seem explicit enough.

During dark adaptation, these processes are reversed. The retina recaptures vitamin A by binding it as retinene in rhodopsin. The increase in retinene concentration during dark adaptation closely parallels the measured increase of rhodopsin concentration (compare Figs. 2 and 4).

With this increase of retinene, there is a reciprocal fall of vitamin A concentration in the pigment layers. The retinal vitamin A, on the other hand, stays relatively constant during the early stages of dark adaptation, and then gradually declines to its dark-adapted level of 4–5 per cent of the total vitamin A.

Dark adaptation is completed in about 100–120 min. I find at this time, however, a small amount of vitamin A in the pigment layers, which gradually disappears over the next few hours. During this time there is no increase of retinene or retinal vitamin A, so presumably this bit of vitamin A diffuses away into the blood stream. The origin and significance of this superfluous vitamin A is obscure.

Vitamin A in both the eye and body may exist in two forms: it circulates in the plasma as the free alcohol, but it is stored in the tissues primarily as the ester. It has been suggested that the vitamin A alcohol of the tissues is in equilibrium with that of the blood, and that through esterification a tissue can concentrate vitamin A independently of this equilibrium²². Krinsky has demonstrated the esterification of vitamin A in the eye tissues of cattle, and has found that much of the vitamin A, both in the retina and in the pigment epithelium, is esterified²³.

It is of interest to inquire as to the state of vitamin A in the pigment layers of the rat after 60 min. of light adaptation. For this, six animals were light adapted for 1 hr., their eyes enucleated, dissected, and the pigment layers extracted for vitamin A, as described above. The ester and alcohol fractions were separated on a column of alumina 'weakened' with 5 per cent water. Esterified vitamin A is eluted from such a column with 4 per cent acetone in petroleum ether, while free vitamin A is eluted with 20 per cent acetone in petroleum ether²⁴. The fractions were assayed for vitamin A by the Carr-Price reaction. In two experiments, it was found that 92 per cent of the vitamin A in the pigment epithelium after 60 min. of light adaptation was esterified. Krinsky found that in cattle 87 per cent of the vitamin A in the pigment epithelium was esterified²⁵.

Fig. 8. The relation between rhodopsin content of the retina and the visual threshold in animals dark-adapted after exposure to bright light, and in animals night-blind due to vitamin A deficiency. In both instances, the same relationship is observed: the log threshold rises linearly with fall in rhodopsin concentration
●, Night blindness; ○, dark adaptation

animals, and I_t and R_t are, respectively, the threshold and rhodopsin concentration in vitamin A-deficient or partly dark-adapted animals.

This result is not wholly unexpected. Wald has pointed out the striking qualitative similarity between the synthesis of chicken iodopsin and rhodopsin in solution, and the course of human cone and rod dark adaptation⁷. This comparison is valid only provided that one compares the logarithm of the visual threshold with the concentration of visual pigment. Wald has also offered a theory which may explain such a relation⁸.

Recently, Rushton *et al.* have made direct measurements of the rise and fall of human visual pigments in the living human eye during light and dark adaptation^{9,10}, and these measurements show a striking parallelism between the course of human light and dark adaptation, and the course of bleaching and re-synthesis of the visual pigments. Again, this relationship is evident only when the logarithm of the visual threshold is compared with the concentration of visual pigment¹¹.

Very recently, Rushton has compared the regeneration of rhodopsin and the course of dark adaptation under the same conditions in a colour-blind subject, and has also found that the logarithm of the threshold falls in parallel with the increase of rhodopsin content in the eye¹².

There have been several previous attempts to correlate the electroretinogram with visual pigment concentration¹³⁻¹⁶, all of which have attempted to correlate the increase of visual pigment concentration with the increase in size of the b-wave potential elicited with a constant test-flash. As Riggs has pointed out, no simple proportionality exists between magnitude of electroretinogram response and the logarithm of stimulus intensity in the vertebrate eye³. Furthermore, the shape of curve obtained by plotting magnitude of response against time in the dark for intensity of a single flash may vary with the luminance of the test-flash selected¹⁶. As can be seen from Fig. 1, if the test light is too dim, one does not begin to record an electroretinogram until considerable quantities of rhodopsin have accumulated in the retina. This may explain why Granit, Munsterhjelm and Zewi failed to record an electroretinogram in the cat until 40 per cent of the visual pigment had

been regenerated¹⁴. In the rat, as we have seen (Fig. 1), one can record an electroretinogram at any concentration of rhodopsin provided that the test stimulus is bright enough.

On the other hand, if the test stimulus were very bright, large fluctuations in rhodopsin might occur with little effect on the size of the electroretinogram potential. A preferable procedure on all counts is to evaluate the sensitivity of the eye by measuring the light intensities required to evoke a constant potential, perhaps most simply as here the just perceptible electroretinogram.

In summary, following 30 min. of intense light adaptation, the rhodopsin concentration of the eye of the rat is lowered to less than 5 per cent of the dark-adapted level, and the electroretinogram threshold has risen about 3.50 log units (about 3,000 times). With time in the dark, the logarithm of the electroretinogram threshold falls in strict parallelism with the rise of rhodopsin concentration. Both log threshold and rhodopsin content of the eye return to the dark-adapted level in about 100 min.

Distribution of Retinene and Vitamin A in the Eye during Light and Dark Adaptation

On exposure to light, rhodopsin bleaches to a mixture of retinene (vitamin A aldehyde) and the protein, opsin. The retinene may then recombine with opsin, forming rhodopsin again, or it may be reduced to vitamin A. After an intense and prolonged light adaptation, almost all the retinene in the eye is transformed to vitamin A¹⁷.

Several years ago, Wald observed in frogs that the bulk of the vitamin A formed after light adaptation disappears from the retina¹⁷. More recently it has been shown that the total amount of retinene and vitamin A in the frog's eye does not vary during light and dark adaptation¹⁸; thus it seemed probable that exchanges of vitamin A occur between the visual cells and the pigmented layers (pigment epithelium and choroid) that lie in contact with them. Probably most, if not all, of these exchanges involve the pigment epithelium, the long processes of which envelop the outer segments of the visual cells. In many animals the pigment epithelium also contains considerable stores of vitamin A, even in the dark-adapted state¹⁷.

Histological evidence for the exchange of vitamin A between retina and pigment epithelium has been obtained by Jancsó and Jancsó¹⁹ and Greenberg and Popper²⁰, who observed typical vitamin A fluorescence in the pigment epithelium of the rat after light adaptation, which disappeared on dark adaptation. In agreement with the latter observations, I have found that the pigment epithelium of the albino rat contains no detectable stores of vitamin A in the dark-adapted state.

The distribution of retinene and vitamin A during light and dark adaptation has not hitherto been studied quantitatively. The albino rat seemed ideally suited for this purpose, both because in this animal the pigment epithelium contains no vitamin A when dark adapted, and because (unlike the frog) the retina readily separates from the back of the eye in either the light- or dark-adapted condition.

For these experiments, groups of animals (weighing 150-200 gm.) were dark adapted overnight, and then brightly light adapted in a white porcelain pan illuminated with three 100-watt flood lamps. For

The experiments were performed in the following way. Groups of animals were light-adapted for 30 min. in a white porcelain pan, brightly illuminated with three 100-watt flood lamps. At selected times after the lights were turned out, an animal was selected at random and the electroretinogram threshold recorded. Each measurement was made with a fresh animal, anaesthetized with nembutal (10–15 mgm.) 5–10 min. beforehand. To prepare for the first measurement (at 3 min.), anaesthetic was given to one animal a few minutes before the end of light adaptation. After an animal was anaesthetized, it could be prepared for the experiment and its threshold determined in about 3 min. Then the electroretinogram was recorded over a luminance-range of 5 log units.

The stimulus was a 1/50 sec. flash of white light, the luminance of which could be varied continuously with circular photographic wedges. The electroretinogram was recorded from the cornea with cotton wick electrodes connected with a Grass P-6 amplifier and Dumont oscilloscope fitted with a camera attachment. Capacity-coupled amplification was used to yield a more stable base line.

To measure rhodopsin, the same or other groups of animals were light-adapted as before on the following day. At appropriate times, an animal was anaesthetized, its eyes removed, and the retinas dissected free and dropped into cold 4 per cent alum solution. The retinas were collected pair by pair in this manner throughout the entire experiment. Each pair of retinas was finally washed twice with water, once again in neutral phosphate buffer, and the rhodopsin was extracted overnight with 0.2 ml. of 2 per cent digitonin. The next day, the extract was centrifuged clear, 0.01 ml. of 1 M hydroxylamine was added, and the absorption spectrum was run in a Cary recording spectrophotometer. The solution was bleached with white light for 5 min., and the absorption spectrum re-run. The difference in extinction at 500 mμ before and after bleaching indicated the concentration of rhodopsin. Measurements of rhodop-

Fig. 1. Electrophoretogram responses during dark adaptation in the rat. The top three lines show the time in the dark; the logarithm of the electroretinogram threshold, the lowest luminance necessary to evoke a perceptible electroretinogram; and the rhodopsin content expressed as percentage of the dark-adapted level. The electroretinograms are evoked with 1/50 sec. flashes of white light over a luminance range of 5 log units. The first row of electroretinograms shows the responses of a control animal, dark-adapted overnight. After light adaptation, the electroretinogram threshold is raised about 3.5 log units, and the responses at high luminances are diminished in size. With time in the dark, the threshold returns to normal, and the responses at higher luminances assume the dark-adapted form.

Fig. 2. Dark adaptation in the rat. Following light adaptation, the fall of the logarithm of the electroretinogram threshold parallels the rise in concentration of rhodopsin. Both the threshold and rhodopsin concentration are back to the dark-adapted level in about 100 min. ●, log threshold, ○, rhodopsin.

sin in rats during dark adaptation have previously been made by Tansley⁵ and Lewis⁶. In all, six complete experiments were performed measuring electroretinogram thresholds, and three complete experiments measuring rhodopsin concentration.

Fig. 1 shows the electroretinogram responses recorded in such an experiment over a range of luminances of 5 log units. At the top of Fig. 1 the time in the dark following light adaptation is shown, and on the next line the logarithm of the electroretinogram threshold, the lowest luminance of light which evoked a perceptible electroretinogram. The normal threshold is set arbitrarily at 1, so that log threshold is 0. The third line shows the rhodopsin content, expressed as percentage of the completely dark adapted level.

The first row of electroretinograms shows the responses of a control animal which had been dark adapted overnight. After 30 min. of light adaptation, the threshold recorded after 3 min. in the dark was raised 3.50 log units (about 3,000 times). The rhodopsin concentration was reduced to 4–5 per cent of the dark-adapted level. With time in the dark, the sensitivity of the eye returned gradually to the dark-adapted state, in parallel with the rhodopsin concentration. Dark adaptation was completed in about 100 min.

Fig. 2 compares the rise in rhodopsin concentration and fall of electroretinogram threshold during dark adaptation. It is seen that the log threshold falls in strict parallelism with the rise in rhodopsin concentration.

Fig. 3 compares the relationship between rhodopsin concentration and log threshold both during dark adaptation and night blindness owing to vitamin A deficiency. It is clear that the logarithm of the electroretinogram threshold, even under these different conditions, rises and falls linearly with the concentration of rhodopsin. This relationship is expressed by the equation:

$$\log I_t/I_0 = 3.6 (R_0 - R_t)/R_0$$

in which I_0 and R_0 are, respectively, the threshold and rhodopsin concentration in dark-adapted control

Fig. 1. Torque curve due to a directed stress of 520 kgm./cm.² on a sample of basalt, suspended in a field of 10.6 kilo-oersteds. Circles are experimental points, line is $\sin 20$ curve

that the application of stress had not produced any permanent anisotropy. Curves of the difference $(T_s(\theta) - T_0(\theta))$ were plotted, showing the expected $\sin 2\theta$ form (2), as in the example in Fig. 1. The values of λ_s determined from $(T_s - T_0)$ using equation (2) are given in column 3 of Table 1.

Table 1. SATURATION MAGNETOSTRICTIONS OF FIVE ROCK SAMPLES

Rock	$(T_s - T_0)$ dyne cm./cm. ³	(λ_s) exp.	I_s e.m.u./cm. ³	(λ_s) calc.
Dolerite	150	0.20×10^{-6}	4.0	$0.2_s \times 10^{-6}$
	150	0.19×10^{-6}	4.0	$0.2_s \times 10^{-6}$
Basalt	710	0.91×10^{-6}	11.1	0.6×10^{-6}
	750	0.97×10^{-6}	11.3	0.6×10^{-6}
Monchiquite	630	0.81×10^{-6}	9.2	0.5×10^{-6}

The saturation magnetic moments I_s of the rocks were also measured and are given in column 4 of the table. These values were used to make crude estimates of the expected magnetostrictions $(\lambda_s)_{calc.}$ (column 5) by assuming that magnetostriction is proportional to I_s :

$$\lambda_s = \lambda_{sm}(I_s/I_{sm}) \quad (3)$$

where λ_{sm} and I_{sm} are values of λ_s and I_s for pure magnetite and are taken as $\lambda_{sm} = 25 \times 10^{-6}$, $I_{sm} = 480$ e.m.u./cm.³. It is reasonable to expect that (3) would be correct for a rock in which the only strongly magnetic mineral is nearly pure magnetite. This is the case with the dolerite specimens, in which 2.0 per cent by volume of the rock is magnetic mineral, approximately half being magnetite with $I_s \sim 400$ e.m.u./cm.³ and half ilmenite, which can be neglected for this purpose. The magnetic minerals in the basalts from Kiama are impure cubic magnetites (L. G. Parry, private communication) for which values of λ_s are not known. However, for the three rock types examined here magnetostriction has the sign and approximate magnitude expected for magnetite-bearing rocks and it is reasonable to take as general the rule that the magnetostriction of a rock may be simply calculated as a weighted sum of the magnetostrictions of its constituent magnetic minerals.

In view of this result, the experiments reported by Stott and Stacey^{3,4} show that when an intrinsically isotropic rock is subjected to stress while cooling in a field it acquires thermo-remnant magnetization in a direction deflected away from the field by such an angle that it returns precisely to the field direction when unloaded.

The determination of saturation magnetostrictions of slightly magnetic materials by the method described above could certainly be used, without modification,

down to $\lambda_s = 10^{-8}$ and appears to be capable of even further development.

GEOLOGY

Charnockite in the Making

EXTENSIVE quarrying is being done on the hill slopes west of Kabbal (12° 30' N., 77° 18' E., situated about 40 miles south-south-west of Bangalore), and so fresh surfaces were available for examination. Peninsular gneiss is the prevailing rock of this region. It is thinly foliated and often highly contorted. The gneiss is generally biotitic; but there are hornblende layers and streaks.

In the middle of the light-coloured banded exposures of gneiss there are small irregular or elongated patches of coarse-grained, greasy, brownish-green rock (Fig. 1). The disposition of these patches bears no relation to the foliation direction of the gneiss, and often runs athwart it. Though the fabric has been affected because of coarser crystallization, it is remarkable that in many of these patches the banding of the gneiss can still be recognized to be passing through them. Crystals of hypersthene exhibiting schiller lustre have been developed in these coarse patches.

From the geological map of Mysore State, it can be seen that the main mass of charnockite occurring in the Biligirirangan Hills and eastwards branches into narrow finger-like projections in the Halagur-Satnur region north of the River Cauvery, an area which was formerly mapped as Closepet granite but which is now known to be composed mainly of Peninsular gneiss. Farther northwards, the charnockites are found in patches of varying sizes, and even these isolated occurrences completely disappear near about lat. 12° 30' N. Kabbal is situated on one such fringe of the huge charnockite massif which includes the Biligirirangan Hills and the Nilgiri Mountains.

Fig. 1. Photograph of a quarry face showing charnockite patches (ch) in Peninsular gneiss (gn). The dark areas in the top left hand of the picture are composed of hornblende inclusions (h) of varying sizes

Fig. 2. A close-up photograph showing parts of contorted Peninsular gneiss (*gn*) becoming converted into charnockite (*ch*). The coarse crystallization has resulted in the partial obliteration of the foliation of the gneiss. The protractor-scale is 6 in. long

Figs. 1 and 2 clearly show that portions of the gneisses are becoming converted into charnockites. When recrystallization has advanced, the gneissic foliation is destroyed; but in the intermediate stages the banding can be traced through the patches getting charnockitized (Fig. 2). In Kabbal, we are apparently on the rim of a charnockitization front where it is possible to have visual demonstration of the successive stages in the transformation of a gneiss to a coarse-grained rock.

The changes can also be followed in thin sections of these rocks. Flakes of biotite in parallel alignment characterize the gneiss. The basic patches are composed mainly of green amphiboles with occasional biotites. When subjected to transformation, a light-green diopside develops from the hornblendes. In the charnockitic patches, coarse hypersthene with the characteristic pink to green pleochroism have been formed. The amphiboles are brownish-green in colour, and the biotites when present are foxy-red.

CRYSTALLOGRAPHY

Super-Cell Structure of Semiconductors

THE structures of many compounds and alloys have been shown to be essentially super-lattices on a few basic lattices. Interest in the diamond structure in particular has been stimulated recently by the technological importance of semiconductors. The best known semiconductors—germanium and silicon—have the diamond structure and many semiconducting compounds of interest have the closely related structures of zinc blende and chalcopyrite. Some work¹ has been done recently in an attempt to list the possible super-lattices of the cubic lattices, but the diamond structure has not yet been considered. The aim of this communication is to introduce a new line of attack on this problem of super-lattices.

The diamond structure consists of two interpenetrant face-centred cubic sub-lattices symmetrically spaced. The zinc blende lattice can be thought of as a super-lattice of the diamond structure in which each of these sub-lattices is occupied by a different atomic species. If the distribution of atoms in zinc blende could be randomized the structure would become a

'defect' diamond structure. (For a discussion of the term 'defect' see ref. 2.) Any adamantine material may in like manner be described as a super-lattice on the diamond structure and its unit cell will be related to the unit cell of diamond. Similar families of compounds can be found based on other basic lattices. I propose to call possible unit cells of super-lattices based on a given lattice 'super-cells' of that lattice, and to illustrate the concept here with reference to the adamantine super-cells. In practice the formation of a super-lattice often leads to a distortion of the original lattice. Since, however, this is often slight I shall neglect it in this treatment and assume that pseudo-cubic symmetry is accurately maintained when a super-lattice is formed. Thus I shall assume in discussing the adamantine super-cells that the atomic sites available are exactly those of a diamond structure.

Table 1 lists the simpler adamantine super-cells. The nomenclature chosen (*C* (cubic), *T* (tetragonal) and *O* (orthorhombic)) denotes the external symmetry of the super-cell in question—which is also the highest symmetry class possible for a substance with this as its unit cell. Super-cells within each of these main groups are numbered in order of increasing size. For simplicity certain less-symmetrical super-cells will not be discussed.

At first sight it might be thought that all super-cells would be built up of simple unit cells and thus that the super-cell dimensions would be simple multiples of the *C1* cell. This is not so, because the conventional unit cell of diamond is not primitive. Thus the *T1* super-cell may be derived from the normal unit cell (here called the *C1* cell) by the standard transformation of face-centred tetragonal to body-centred tetragonal. This cell is still not

Table 1. SIMPLER ADAMANTINE SUPER-CELLS

	O15	$1/\sqrt{2}$ $3/\sqrt{2}$ 3	36	O30	$3/\sqrt{2}$ $2\sqrt{2}$ 1	48

The super-cell dimensions are given in units of the simple unit cell parameter 'a'.

Table 2. SOME TYPICAL ADAMANTINE COMPOUNDS LISTED BY SUPER-CELLS

Super-cell	Adamantine compound
C1	C (diamond), Si, Ge, Sn (grey) ZnS (blende) and more than 30 analogues including the III-V, II-VI, and certain I-VII compounds CdIn ₂ □ Se ₄ and Cu ₂ Hg□I ₄
C2	Cu ₂ SbS ₂ (tetrahedrite), Cu ₂ SbS ₂ and related compounds
T5	CuFeS ₂ (chalcopyrite) and its analogues Cu ₂ FeSnS ₄ (stannite) Many II III ₂ □VI ₄ compounds
T16	Holmes structure for In ₂ Te ₂ (not strictly adamantine) (see ref. 7)
O2	Woolley and Pamplin's structure for In ₂ □Te ₂
O3	Ga ₂ □Hg ₂ Te ₂ and In ₂ □Hg ₂ Te ₂ (possibly)

□ is the symbol for a vacant lattice site.

primitive—the primitive cell of diamond is in fact a rhombohedral one and so not listed in Table 1.

Table 2 shows some typical adamantine materials listed by means of their super-cells. A fuller discussion of the inter-relationship of the adamantine compounds can be found in ref. 3.

A general formula for an adamantine compound can be written thus:

$$A_a B_b C_c \dots X_x Y_y Z_z \dots$$

where $a, b, c, \dots x, y, z, \dots$ are the relative numbers of $A, B, C, \dots X, Y, Z, \dots$ atoms in the compound. The elements $A, B, C, \dots$ come from any of the first four B sub-groups of the periodic table, while $X, Y, Z, \dots$ come from the remaining B sub-groups (omitting, of course, the rare gases). The formula is valid as a candidate for the diamond structure provided that there are on average four valence electrons per site. This requires that:

$$\frac{\sum_i n_i v_i}{\sum_i n_i} = 4$$

where n_i is the number of atoms of the i th kind, with v_i electrons in its outer shell. Vacant sites must be counted, and for these v_i is zero. This provides a necessary, but not sufficient, condition for the existence of an adamantine material. It is readily seen that the Mooser and Pearson rule⁴ is satisfied, and so all adamantine materials will be expected to be semiconductors.

I have calculated³ the various classes of intensity of X-ray reflexions which are to be expected from a C1 and a C2 super-cell in which all the atomic sites are assumed different. The results can readily be applied in the analysis of any new super-lattice which may be described on either of these unit cells. The C2 super-cell is especially interesting because it includes the smaller super-cells C1, T1, T2, T5, T6, T13, T14, O1 and O3, and thus embraces most of the common adamantine compounds.

The study of solid solutions between compounds of the zinc blende type has already yielded several new examples of super-lattices. Super-cells may be used to predict compositions at which ordering may occur. Ordering will be possible on a given super-cell only if the number of sites available in that super-cell is correlated with the composition of the alloy. Consider, for example, alloys of two zinc blende compounds MX and NY. A general alloy may be written:

Ordering on a C1 cell is possible for $x = \frac{1}{4}, \frac{1}{2}$ or $\frac{3}{4}$. Ordering on a T3 or O2 cell is possible for $x = \frac{1}{4}, \frac{1}{2}, \frac{3}{4}$ or $\frac{3}{4}$. Also on a T4, T5, T6, O3 or O4 cell for $x = \frac{1}{4}, \frac{1}{2}, \frac{3}{4}, \frac{1}{2}, \frac{3}{4}, \frac{3}{4}$ or $\frac{3}{4}$. Thus the most likely compositions for ordering are $x = \frac{1}{2}, \frac{1}{4}$ or $\frac{3}{4}$, while $x = \frac{1}{4}$ (requiring, for example, a T7 or O5 super-cell) is much less likely to be an ordering composition. If ordering is suspected at a particular composition then a consideration of the possible super-cells enables one to predict the pattern of super-lattice lines which will occur. For example, if $x = \frac{1}{4}$ is thought to be an ordered phase, then the super-lattice powder lines should be indexed at first on a threefold cubic cell (C3). From the absences which occur it should be possible to decide between T3 and O2.

Another use of super-cells is in the examination of alternative structures. Chalcopyrite, CuFeS₂, was originally assigned a tetragonal structure based on a distorted C1 cell⁵. Fifteen years later Pauling and Brockway⁶ showed that the now generally accepted structure based on a T5 super-cell gave better agreement with the X-ray data. Many of the recently discovered ordered adamantine materials may perhaps need a similar revision. A systematic examination of the possible adamantine super-lattices is a desirable starting point for a critical survey of the known materials as well as for the prediction of new ones.

Super-cells should also prove useful in discussing the effects of ordering on the properties of a material, because changes in shape of the Brillouin zone due to ordering may be deduced from X-ray intensity calculations.

A fuller discussion including details of the X-ray intensity calculations will be published elsewhere in due course.

I wish to thank Dr. J. C. Woolley and Dr. S. Wallwork for helpful discussions.

METALLURGY

Determination of Silver in Lead Concentrates by Atomic Absorption Spectroscopy

THE fire assay method is used universally for the determination of silver in ores and concentrator products. This method, which is capable of very high precision, is subject to a loss of silver during cupellation, and corrections for this loss, if made, must be on an empirical basis depending on the conditions of cupellation¹⁻³. Walsh⁴ showed that atomic absorption spectroscopy offered possibilities as an absolute spectrochemical method freed from the necessity of using chemically analysed standards or synthetic samples the composition of which approximated that of the unknown. Several papers⁵⁻⁷ on the application of atomic absorption spectroscopy to

the determination of cations in solution have been published. These papers showed that, in general, the atomic absorption technique was free from inter-element effects and required the minimum amount of manipulation. Lockyer and Hames⁸ directed attention to the possibility of determining the noble metals by atomic absorption spectroscopy and quoted a limit of detectability of 0.1 p.p.m. for silver.

We have studied the application of this technique to the determination of silver in the lead-silver-zinc ores and concentrator products at the Zinc Corporation Ltd., Broken Hill, Australia. Special emphasis has been placed on the determination of silver in lead sulphide concentrates containing approximately 550 p.p.m. (18.0 oz. per ton) silver.

The apparatus used was basically the same as that described by Box and Walsh⁹. Initially an EEL flame photometer burner giving a 2.5-cm. flame path was used. In order to obtain satisfactory absorption readings it was necessary to use silver concentrations of between 10 and 15 p.p.m. This meant that the silver content of 1 gm. of lead concentrate had to be taken into solution in a final volume of 50.0 ml.

Lead at the concentration of 20,000 p.p.m. was shown to have no effect on the absorption due to silver. It was therefore decided to try to eliminate completely all separations.

A number of unsuccessful attempts were made to devise a method based on complete solution of all components in the sample. Techniques which involved the formation of lead sulphate resulted in a loss of silver by adsorption.

The method finally selected was based on the solution of the lead concentrate in concentrated hydrochloric acid, measurement of atomic absorption being made in a 25 per cent v/v hydrochloric acid, 3 per cent v/v nitric acid solution. The standards used were solutions of pure silver in 25 per cent v/v hydrochloric acid run concurrently with each batch of test samples.

Trouble from two sources was experienced when working at these high acid concentrations and with solutions saturated with lead chloride. The stainless steel inlet capillary of the EEL atomizer corroded rapidly, and at the same time lead chloride was precipitated in it. Substitution of a glass inlet capillary eliminated the trouble due to corrosion. To eliminate the precipitation of lead salts in the capillary it was necessary to adjust the conditions so that the final analysis solution, while having a silver concentration of 10-15 p.p.m., was unsaturated with lead chloride.

Table 1 shows a comparison of the silver results obtained by the fire assay and atomic absorption methods on five samples of lead concentrate. Each atomic absorption run was made on a different day. The fire assay results are the average of four determinations and are uncorrected for silver lost during cupellation.

Table 1. THE SILVER CONTENT (OZ./TON) OF LEAD CONCENTRATES

Sample No.	Atomic absorption Run					Mean	Fire assay
	1 (a)	2 (a)	3 (b)	4 (b)	5 (b)		
1	18.25	18.23	17.98	17.90	17.90	18.05	17.35
2	16.59	16.73	16.58	16.45	16.55	16.58	16.25
3	17.08	17.03	16.98	16.55	16.70	16.87	16.60
4	17.68	17.84	17.69	17.50	18.05	17.75	17.30
5	17.62	17.62	17.49	16.90	17.60	17.45	16.70

a, Analyst A; b, analyst B.

The standard deviation of the atomic absorption results is 1.14 per cent relative. They indicate that atomic absorption spectroscopy offers a rapid and precise means of determining silver in lead concentrates, giving results approximately 0.5 oz. per ton higher than the uncorrected fire assay result at this level.

A more detailed account of this work will be submitted to the Institution of Mining and Metallurgy and the Australasian Institute of Mining and Metallurgy.

Cathodic Cleaning of Metals before High-Temperature Oxidation

SINCE metallic oxidation is a surface phenomenon, the preparation of the surface prior to the oxidation experiment is very important. If the method of preparation produces a thin film of oxide or another compound on the surface, the subsequent oxidation may be affected. Thus, Vernon, Akeroys and Stroud¹ found that the rate of oxidation of zinc below 225° C. was different for abraded, etched or electrolytically polished surfaces. For fundamental work, the ideal is to commence the oxidation with a film-free surface. This was done in the case of iron by Davies, Evans and Agar². The iron was reduced in hydrogen at 480° C., and after this gas had been removed by evacuation, oxygen was introduced. However, it is not possible to carry out this procedure with all metals. Thus the oxide of tin cannot be reduced by hydrogen below the melting point of the metal. The oxidation of solid tin cannot therefore be carried out on an initially film-free surface.

When this is not possible, a method of preparation must be found which is relatively easy to carry out and which also gives reproducible results. One such method is that of cathodic cleaning, with sodium carbonate as an electrolyte, and this has been used in the case of tin. The advantages of the method are: (1) traces of grease are mechanically removed by the hydrogen produced; (2) any oxide film on the surface is reduced to the metallic state. When the specimen is then taken out of the solution, washed and dried, a new oxide film forms on the surface when it is exposed to air. It is reasonable to assume that, provided the specimens have been kept in a desiccator, the thickness of this film is the same each time. Hence the oxidation experiment can be carried out on a surface carrying a thin oxide film of constant thickness.

CHEMISTRY

Phase Diagram of the System Vanadium Pentoxide - Boron Trioxide

However, experiments on tin of 99.9999 per cent purity in this laboratory have shown that the mechanism is more complicated than formation in air of a simple film, and can give misleading results. The tin specimen, 5 cm. $\times$ 1.6 cm. $\times$ 0.01 in. thick, was made the cathode in a 0.1 M solution of sodium carbonate with a platinum gauze as anode. A current of 80 m.amp. was supplied from a 12-V. battery for a total time of 14 min. (7 min. each side of specimen facing the anode). The specimen was removed with the current still on, washed with water, then with alcohol and allowed to dry. Such a specimen oxidized at 200° C. for 4 hr. remained bright, whereas an untreated specimen showed mauve interference colours. It is apparent that a film, which interferes with the subsequent oxidation, forms on the tin as a result of the cathodic treatment. The thickness of this film can be determined electrometrically, using a de-aerated solution of 0.005 M potassium chromate in the apparatus described by Mills and Evans³. The potential of the specimen (cathode) versus a silver-silver chloride reference electrode is measured periodically until the end-point is reached, that is, when the potential changes from that due to oxide reduction to that corresponding to evolution of hydrogen. The number of millicoulombs required for the reduction of the oxide can be taken as a measure of film thickness. The film thickness calculated on this basis is given in Table 1 for specimens oxidized at 200° C. for various times, together with the interference colour.

Time (hr.)	Before treatment	After treatment
1	11 (no interference colour)	4.4 (no interference colour)
2	19 (yellow)	5.9 "
3	23.5 (light brown)	7.3 "
4	27.5 (mauve)	10.7 "

The film thickness on the untreated specimen after 1 hr. at 200° C. is slightly greater than after 4 hr. of oxidation for the treated specimen.

The film thickness before and after cathodic treatment can also be determined electrometrically. It was found to correspond to 3.47 millicoulombs before treatment and to 2.0 millicoulombs after treatment. Thus the thinner film produced as a result of the cathodic treatment has a much greater influence on the subsequent oxidation than the original film, reducing the rate of oxidation by about one-third. It is obvious that the two films are different, and that cathodic treatment of tin before the high-temperature oxidation of the metal gives results which are not characteristic of the metal itself.

It is possible that this applies to the other metals as well. Therefore, the possible effect of cathodic cleaning on the metal should first of all be investigated, in order to avoid producing misleading results in the subsequent oxidation experiments. In the case of tin, the formation of the resistant film during cathodic treatment is dependent on time of treatment, applied voltage and nature of electrolyte.

In a previous communication I reported on the investigation of the system vanadium pentoxide-phosphorus pentoxide¹. A similar method has been applied in the examination of the system vanadium pentoxide-boron trioxide. The present report describes the liquidus curve of the system vanadium pentoxide-boron trioxide, together with the results of X-ray investigations of the fine structure. The liquidus curve was established by a special differential thermoanalytical apparatus described in detail in a former communication². The heating curves of five samples are presented in Fig. 1. The composition of these samples was as follows—vanadium pentoxide + boron trioxide, percentages by weight: (1) 95 + 5; (2) 90 + 10; (3) 85 + 15; (4) 70 + 30; (5) 55 + 45.

Apart from the melting point, no other maxima indicating conversion or eutectics appear in the heating curves. The melting point decreases with the rise of content of boron trioxide.

X-ray investigations of fine structure were carried out by the Debye-Scherrer method. The structure of eight samples of various composition was examined. The composition of these samples was as follows—vanadium pentoxide + boron trioxide: 95 + 5; 90 + 10; 80 + 20; 65 + 35; 55 + 45; 50 + 50; 45 + 55; 35 + 65.

The boron trioxide used in preparing these samples was crystallized by a method similar to that applied in the heat treatment of the samples. The lines of the powder diagram, established for the crystals of the product obtained in this way, and also the lines of vanadium pentoxide³, were found in the powder diagrams of all samples examined. Apart from the lines of the two types of crystals mentioned, no

Fig. 1

Fig. 2

other interference lines indicating the presence of a third phase were observed.

As the presence of boron trioxide can be detected even in samples containing only 5 per cent of the compound, and as in the sample containing 65 per cent boron trioxide, apart from this compound, only vanadium pentoxide can be detected, the system vanadium pentoxide - boron trioxide cannot be regarded as a eutectic system.

Fig. 2 shows the phase diagram plotted on the basis of the heating curves revealed in Fig. 1, and of the results of the X-ray investigations of fine structure.

True Reactivity of the Organocadmium Compounds

WHILE studying the chemistry of the organocadmium compounds, evidence was found making necessary a revision of accepted views regarding their reactivity and indicating that a 'salt effect' plays a critically important part as a catalyst in their reactions. Organocadmium compounds are generally considered to be very reactive with acid chlorides, but practically inert towards aldehydes and ketones¹, thus making possible the important 'organocadmium synthesis' of ketones^{1,2}.

Although twenty-four years have elapsed since the discovery of this synthesis by H. Gilman, there is no record in the literature of any attempt to use isolated, pure organocadmium compounds to effect the ketone synthesis. Without any exception, the *in situ* reaction mixtures, as obtained by the metathetical reaction of the organomagnesium compounds with cadmium salts, have been used. Therefore, I tried to repeat the acetophenone synthesis of Gilman and Nelson¹ with the difference that pure dimethylcadmium³ was used instead of the *in situ* reaction. The surprising result was that benzoyl chloride did not form acetophenone with pure distilled dimethylcadmium. (Benzene or ether solution, reaction time 2 hr. at 40°.) 92 per cent of the benzoyl chloride remained unattacked as shown by saponification to benzoic acid. Moreover, under similar conditions,

only slight reactivity was observed between benzoyl chloride and distilled diethylcadmium, dibutylcadmium and recrystallized (free from magnesium salt) diphenylcadmium, respectively. When distilled diethylcadmium was treated with acetyl chloride (benzene solution, reaction time 20 min. at 28°), 79 per cent of the diethylcadmium remained unchanged.

In all the recorded cases in the literature, mixtures of the organocadmium compounds and the magnesium salts were used to effect the ketone synthesis; hence my negative findings suggest that in Gilman's original experiments¹ as well as in the hundreds of other ketone syntheses described with the use of organocadmium compounds, a hitherto unrecognized 'salt effect' exerted an unintentional, and in many cases indispensable, activating effect. This salt effect could have been caused by the magnesium salts generated in the usual preparation of the organocadmium compounds:

The activation hypothesis was supported by the finding that benzoyl chloride produced acetophenone in 74 per cent yield on treatment with distilled dimethylcadmium in the presence of one mole of magnesium bromide. Furthermore, diethylcadmium, dibutylcadmium and diphenylcadmium reacted with benzoyl chloride in the presence of magnesium bromide and magnesium chloride, respectively, giving the corresponding ketones in yields of 60-80 per cent (conditions the same as before). The reaction of acetyl chloride (2 mol.) with distilled diethylcadmium (1 mol.) was complete (97 per cent) when two moles of magnesium bromide etherate were present (benzene solution, 20 min. at 28°). With a longer reaction time (3 hr.), this last reaction goes to completion even in the absence of magnesium salts. In contrast, using less reactive organocadmium compounds, the magnesium salts influence not only the velocity but also the direction of the reaction. Thus, an enforced reaction of benzoyl chloride with dimethylcadmium (5 hr. at 82° in benzene) resulted in a complex mixture of products, with only 20 per cent of acetophenone.

The salt effect influences the reactivity of aldehydes also: benzaldehyde showed only 19 per cent conversion with distilled diethylcadmium in ethyl ether (100 hr. at 25°), but 86 per cent conversion (into phenyl-ethyl-carbinol) in 1 hr. using a diethylcadmium solution prepared from ethylmagnesium bromide and cadmium chloride. These results explain the observations of Gilman¹ with regard to the relative reactivities of aldehydes and acid chlorides with organocadmium compounds; salt-free diethylcadmium was employed in the experiment with benzaldehyde, but even after five months the reaction was incomplete; an *in situ* mixture of the organocadmium compounds and magnesium halides was used in the ketone syntheses.

The elucidation of the difference between the reactivity of the genuine organocadmium compounds and the *in situ* mixtures containing magnesium salts means that we should differentiate between organocadmium chemistry, as at present known, and the chemistry of the genuine organocadmium compounds, which still remains to be studied. The reaction of tertiary alkylhalogenides and organocadmium compounds, as my preliminary experiments indicate, are subject to a catalysis by magnesium salts

also. Therefore, the re-evaluation of the results of J. Cason and R. J. Fessenden⁴ seems to be desirable.

William G. Dauben and John W. Collette⁵ discussed an abnormal organocadmium reaction, proposing a mechanism for the reaction of arylcadmium compounds with acid chlorides in which an internal Lewis-acid type intermediate of the class of the acylonium salts was postulated. Neither this hypothesis nor other speculations regarding the reaction mechanism or organocadmium reactions⁶ considered the catalytic role of magnesium salts in the ketone synthesis although invariably present. Cason and Reist⁷ suggested, without any experimental proof, that among others perhaps the magnesium salts could influence the reaction of alkylcadmiums with succinyl dichloride. They supposed that the presence of magnesium salts promotes the side-reaction leading to esters, instead of the normally expected ketones. This assumption contrasts with all of our experimental findings, indicating that magnesium salts promote the formation of ketones, thus diminishing the side reaction.

The recognition of this activation effect opens the way to a planned regulation of the reactivity of organocadmium compounds. It is possible to activate an organocadmium compound in a preselected degree, depending on the type of salt employed. H. Gilman¹ tried unsuccessfully to obtain α -keto esters by the reaction of ethyl chloro-oxalate with diethylcadmium:

I tried the same reaction (with $\text{R}-\text{CH}_3$ or $n\text{-C}_4\text{H}_9$) with lithium bromide as the activator instead of the magnesium salts, which are apparently too active. 8.7 gm. (100 m.moles) of lithium bromide in 35 ml. of tetrahydrofuran was added to 13.7 gm. (100 m.moles) of ethyl chloro-oxalate in 10 ml. of tetrahydrofuran at -30° . 7.1 gm. (50 m.moles) of dimethylcadmium in 20 ml. of tetrahydrofuran was added at -65° in 1 hr., and stirred another hour at -65° . The tetrahydrofuran was distilled off *in vacuo* at 25° , the residue taken up in water, extracted with ether, the combined ether and tetrahydrofuran solutions freed of solvents, and the residue fractionated at a pressure of 18 mm. mercury. At $52\text{--}53^\circ$, 5.90 gm. (51 per cent theoretical yield) of ethyl pyruvate was obtained; phenylhydrazone (m.p. $114\text{--}115^\circ$, mixed melting point with authentic material $115\text{--}116^\circ$). Similarly, at -40° , substituting dibutylcadmium for the dimethylcadmium, ethyl α -ketohehexanoate was obtained in 70 per cent yield. This is the first generally applicable organo-metallic synthesis of this type of compound; for Stacy and McCurdy⁸, using an *in situ* organocadmium solution, obtained only traces of ethyl α -ketohehexanoate from the reaction of dibutylcadmium with ethyl chloro-oxalate, although in special cases, with hindered arylcadmium reagents, yields were much better.

As the preparation of pure, distilled organocadmium compounds is somewhat cumbersome, the description of an experiment where this is avoided is given here. From 1.35 gm. of lithium metal and 11.6 gm. of butylbromide, an ethereal solution of butyllithium was prepared at -30° . The 'double titration' method indicated that 68 m.moles of butyllithium was formed. This was transformed into a dibutylcadmium solution by admixing 9.3 gm. (34 m.moles) of cadmium bromide. After 30 min. stirring at 35° ,

the ether was distilled off *in vacuo* at room temperature, the residue dissolved in 45 ml. of tetrahydrofuran, and this solution, containing 34 m.moles of dibutylcadmium and 152 m.moles of lithium bromide, treated as above with ethyl chloro-oxalate. Ethyl α -ketohehexanoate was obtained in a yield of 68 per cent of theoretical (7.44 gm.).

I have found that magnesium salts exert a similar 'salt effect' in the reaction of the organozinc compounds. Obviously, a potential activation of organo-metallic reactions could always be considered if salts are present in the systems employed. The Grignard compounds are of special interest: Raymond E. Dessy and co-workers⁹ have demonstrated that ethereal solutions of ethylmagnesium bromide contain a complex with the formula $(\text{C}_2\text{H}_5)_2\text{MgMgBr}_2$ (and not the usually considered $\text{C}_2\text{H}_5\text{MgBr}$). Similarly, phenylmagnesium bromide solutions contain only the species $(\text{C}_6\text{H}_5)_2\text{MgMgBr}_2$. The usual higher reactivity of Grignard compounds as compared with the lower reactivity of the R_2Mg type compounds apparently represents another important case of activation of organometallic reactions by magnesium salts.

The mechanism of these reactions is being studied and experiments are being continued to apply the 'selective activation principle' to develop syntheses for other classes of compounds hitherto inaccessible by organometallic synthesis.

Detection of Iodine Compounds by Paper Chromatography

Kolthoff and Sandell¹ have found that minute amounts of iodine as iodide can be detected and determined by the ceric sulphate-arsenious acid reagent:

They have pointed out that the effect of iodides on the reduction of the ceric ion by arsenite is catalytic.

Bowden, MacLagan and Wilkinson² have described methods for the detection of inorganic and organic iodine-containing compounds on paper chromatograms using the ceric-arsenious reaction. The positions of iodine-containing compounds were indicated by white spots on a yellow background. A difficulty encountered in this reaction is the fading of the chromatograms after some minutes due to the presence of small traces of atmospheric iodine.

We have overcome these disadvantages by exposing the chromatograms, immediately after development,

to vapours of a 50 per cent phenol solution and then drying in air; the white spots of iodine-containing compounds are fixed and a marked contrast against dark brown background is obtained. This seems to be due to the oxidation of phenol by the excess of ceric sulphate.

Under similar conditions α - and β -naphthols give white spots with a violet tinge, against a yellow background. Unfortunately these spots are not so easily obtained as those of phenol.

Gas Chromatography of Unesterified Fatty Acids using Polyester Columns treated with Phosphoric Acid

The gas chromatography of unesterified fatty acids was first reported by James and Martin¹, who used a column liquid phase of silicone oil containing 10 per cent stearic acid. Beerthuis *et al.*² extended this work to higher fatty acids (C_{12} and higher) using silicone oil plus β -anthraquinone carboxylic acid and 'Apiezon L' grease as liquid phases. With these systems, considerable tailing of the peak occurs and extremely high column temperatures are required. The association phenomenon of the carboxyl group is responsible for the difficulty of the analysis.

More recently, several authors³⁻⁵ have separated fatty acids of lower molecular weight using more polar liquid phases such as dioctyl sebacate plus sebacic acid³ and polyesters of dibasic acids and glycols^{4,5}.

The extension of polyester phases to the analysis of higher fatty acids (C_{12} - C_{22}) would be advantageous because unsaturated could be separated from saturated acids at lower temperatures than with other phases. The disadvantages of polyesters are their poor thermal stability and high 'bleed' at temperatures higher than 220°C. Furthermore, the polyesters alone are not acidic enough to overcome com-

Fig. 2. Chromatographic analysis of a commercial oleic acid. Flash heater 270°C., column temperature 230°C., helium pressure 16 p.s.i., column size 100 cm. $\times$ 4 mm., hot-wire detector, sample size 3 μ l.

Fig. 3. Chromatographic analysis of the methyl esters of a commercial oleic acid. Flash heater 270°C., column temperature 180°C., helium pressure 16 p.s.i., column size 100 cm. $\times$ 4 mm., hot-wire detector, sample size 1 μ l.

pletely the association phenomenon of the higher acids.

With a column having a polyester treated with phosphoric acid as the liquid phase, well-defined symmetrical peaks were obtained with C_4 - C_{22} acids. Saturated and unsaturated acids were separated from each other. Separations were made at relatively low column temperatures of 220-235°C., and the columns appear to be extremely stable at these temperatures, being usable for several weeks with little loss in efficiency. At 180°C. methyl esters are also separable on the same columns with good peaks.

The column packing was 25 per cent (w/w) diethylene glycol adipate polyester⁶ ('Lac-2-R-446', Cambridge Industries Co., Inc., 101 Potter Street, Cambridge 42, Mass.) and 2 per cent phosphoric acid (85 per cent H_3PO_4) on 60-80 mesh, acid-washed 'Celite 545'. The polyester was dissolved in chloroform and the 'Celite' added. Then the phosphoric acid was added to the slurry, the chloroform was removed by evaporation on a steam-bath with constant stirring, and the powder was placed in a vacuum oven at 60°C. for 24 hr. The coated

Fig. 1. Chromatographic separation of a mixture of long-chain fatty acids. Flash heater 270°C., column temperature 235°C., helium pressure 16 p.s.i. (45 ml./min.), column 100 cm. $\times$ 4 mm., hot-wire detector, sample size 3 μ l.

'Celite' was finally vibration-packed in a copper U-tube (100 cm. $\times$ 4 mm.) and was conditioned for 16 hr. at 220° C. The gas chromatographic instrument was one of my own design utilizing Gow-Mac filaments for thermal conductivity detection.

The separation of a synthetic mixture of fatty acids from C₁₂ to C₂₂, including some unsaturated acids, is shown in Fig. 1. The incomplete separation of the stearic and oleic acid peaks typical of this polyester could probably be improved by lengthening the column or by using another treated polyester. Fig. 2 shows the analysis of a commercial oleic acid at 230°, and Fig. 3 the analysis of the methyl esters of the same acid at 180° C. The fatty-acid sample was three times (3 λ) as large as the methyl-ester sample (1 λ) in order to achieve approximately the same thermal conductivity response.

Table 1. COMPARATIVE GAS CHROMATOGRAPHIC ANALYSIS OF A COMMERCIAL OLEIC ACID AND ITS METHYL ESTER

Acid	Free acid (per cent)	Methyl ester (per cent)
C ₁₀	0.2	0.1
C ₁₂	0.3	0.1
C ₁₄	5.7	4.8
C ₁₄ (¹)	2.7	2.1
C ₁₆	4.2	3.9
C ₁₆ (¹)	6.4	5.6
C ₁₈ (²)	1.2	1.4
C ₁₈ (¹)	75.3	77.2
C ₁₈ (²)	4.2	4.8

Table 1 compares the analyses calculated from the areas under the peaks in Figs. 2 and 3. The differences in the analyses may be due to differences in thermal conductivity of esters and acids. Further work will be required to relate the peak areas of the free acids to true weight percentages of the various acids in the samples.

The polyester phase treated with phosphoric acid gives excellent separations and symmetrical peaks for the higher fatty acids. It should find many applications in biochemical and plant-control work. These liquid phases seem particularly stable to heat, possibly because of ester formation between phosphoric acid and the hydroxyl groups of the polyester.

This work will be described more fully elsewhere.

BIOCHEMISTRY

Effect of Some Benzimidazoles on a Vitamin B₁₂-requiring Alga

THE identification of 5:6-dimethyl benzimidazole (I) as an acid degradation product of vitamin B₁₂ was made in 1949 by Brink and Folkers¹ and independently by Holiday and Petrow². The latter authors also speculated on the biogenesis of vitamin B₁₂ and riboflavin, and suggested the possibility of their common derivation from 4:5-dimethyl-o-

I

II

III

phenylenediamine (II)—a chemical precursor of (I). Furthermore, both these compounds were shown by Emerson *et al.*³ to possess vitamin B₁₂-like activity in the rat. McNair Scott, Rogers and Rose⁴ tested 49 substituted benzimidazoles on several bacterial systems—including the vitamin B₁₂-requiring *E. coli* 113-3. In particular, they found that —SH and —NO₂ substitution in the 4-position was associated with competitive vitamin B₁₂ antagonism. More recently, Timmis and Epstein⁵ demonstrated that 4,5,6-trichloro benzimidazole and its corresponding 1- β -D-ribofuranosyl were non-competitive and competitive antagonists respectively in the highly sensitive vitamin B₁₂-dependent flagellated green alga *Euglena gracilis* var. *z*.

A large series of benzimidazoles was synthesized in 1952 by Feitelson *et al.*⁶, *inter alia* for the purpose of discovering vitamin B₁₂ antimetabolites which might prove of value as chemotherapeutic agents in the treatment of cancer. The object of the present communication is to report the results of some growth-response tests with these compounds on the *E. gracilis* system.

Approximately 140 benzimidazoles were tested using techniques already described^{5,7,8}. On preliminary examination, none was found to support algal growth in the absence of vitamin B₁₂, while 20 produced significant inhibition at low vitamin concentrations. The majority of the latter compounds were tested in subsequent assays to determine whether their inhibitory effects could be reversed or partially reversed by massive concentrations of vitamin B₁₂.

As can be seen (Table 1) no example of competitive or reversible antagonism was detected—a finding possibly related to the observation that (I) does not possess a vitamin B₁₂-like effect in *E. gracilis*.

Four benzimidazoles—Nos. 15, 16, 33 and 103—proved to be surprisingly toxic irreversible antagonists and at concentrations of less than 15 μ gm./ml.

* Examined as hydrochloride.

produced 50 per cent inhibition of growth in the presence of up to 1,000 $\mu\text{gm./ml.}$ of vitamin B₁₂. These compounds generally possess chloroalkyl groups in the 1- and/or 2-positions and chlorine substituents in the 5- and/or 6-positions. It is of interest to note that compound No. 101—designated by Feitelson *et al.*⁶ in 1952 as “a novel type of nitrogen mustard”—was afterwards shown by Hirschberg, Gellhorn and Gump⁹ to be highly toxic to both human and mouse brain tumour cells in tissue cultures. The enhancement of toxicity associated with progressive chlorine substitution on the benzene ring is strikingly exemplified by a comparison of the activities of compounds Nos. 101, 33 and 103 (Table 1). Since in all probability substitution of this type would lead to increased fat solubility, these differences in biological reactivity may well be associated with differences in the ratios of relative solubilities of these compounds in lipids and water. Such a mechanism has been suggested by Timmis and Hudson¹⁰ in relation to the neutropenic effect of two homologous series of $\alpha\Omega$ dimethanesulphonyl-alkanes.

I acknowledge the receipt of a British Empire Cancer Campaign grant. Dr. V. Petrow (B.D.H., Ltd., London) kindly supplied the compounds tested.

Enzymatic Transformation of Dehydroascorbic Acid to Diketogulonic Acid

THE conversion of dehydroascorbic acid to diketogulonic acid has been studied in chemical systems¹; but, as Harris² has pointed out, definite evidence is not available for any enzymatically catalysed transformation.

A search by us has shown that cauliflower (*Brassica oleracea botrytis*) and bitter gourd (*Momordica charantia*) possess an enzymatic mechanism for the conversion of dehydroascorbic acid to diketogulonic acid. The technique of investigation consisted in incubating homogenates with dehydroascorbic acid and following the course of reaction by estimating the amount of substrate disappearing and diketogulonic acid formed by the 2:4-dinitrophenylhydrazine method³. A system made up from heat-treated plant material was run simultaneously as control, and provided data for non-enzymic transformation. The homogenate was prepared by grinding the tissue with cold acetate buffer in a chilled Waring blender,

Table 1. ENZYMATIC TRANSFORMATION OF DEHYDROASCORBIC ACID TO DIKETOGULONIC ACID IN CAULIFLOWER AND BITTER GOURD

		Diketogulonic acid formed (per cent)	Dehydroascorbic acid disappearing (per cent)
No. 1	Cauliflower Experimental	12.0	14.8
	Control	6.2	9.9
No. 2	Experimental, with added Mn ⁺⁺ , final concentration 0.001 M	12.4	13.0
	Control	5.7	5.7
No. 3	Bitter gourd Experimental	8.9	10.1
	Control	2.9	2.9
No. 4	Experimental	17.9	17.9
	Control	9.5	8.3

straining through muslin and making up to 20 per cent (w/v). In a typical assay 10 ml. of the enzyme, or the heat-treated, preparation was incubated with 3,000 $\mu\text{gm.}$ of dehydroascorbic acid, the final volume being made to 30 ml. with buffer after adding any supplements. 5-ml. aliquots of the mixture were analysed at zero time and at the end of 60 min. of incubation at 37° C.

Results recorded in Table 1 show that whereas spontaneous transformation of dehydroascorbic acid to diketogulonic acid occurred in all experiments, enzymic conversion also occurred, as evidenced by the fact that the transformation in the untreated homogenates was significantly higher than in the heat-treated controls.

Specific Protein of Legumes which reacts with Animal Proteins

INTERACTIONS of proteins among themselves, except immunological reactions, can be studied by various methods; but only in a few exceptional cases could they be demonstrated, as in the reactions of trypsin inhibitors and of agglutinins of legumes. Whether the isohæmagglutinins in man are the result of immunization or are a direct product of the participation of blood-group genes has not yet been fully settled. But the proteins which are contained in some plants and agglutinate erythrocytes cannot be a result of immunization; they are, so to speak, natural antibodies. An antibody, however, is defined as a substance produced in response to an antigen. In this regard an antibody produced not in response to an antigen is self-contradictory. To avoid such confusion, Boyd¹ proposed the term ‘lectin’ for such substance as is produced not in response to an antigen but reacts more or less specifically with certain proteins or antigens.

It is already well established that agglutination and the precipitation can be caused by one and the

same antibody. Therefore the agglutinating 'lectin' can probably precipitate appropriate substances, and the distinction between agglutinating and precipitating 'lectin' may not be necessary. However, it is interesting that hitherto observations were made only on the agglutinating 'lectins' of plants. One of the reasons lies probably in the fact that the agglutination of erythrocytes is very sensitive. The second reason might be that such substances can be expected to be used as test substances for blood groups, while no direct application could be expected of a 'precipitating lectin'. On the other hand, observation of a precipitating 'lectin' is not always easy, because the formation of precipitate can also be caused by reactions other than a direct reaction of a protein with other proteins, for example, by the change of pH and/or salt concentration and so on.

In any event it was hoped that among the proteins of remote phylogenetic origin, there might be some which bind fairly firmly with each other, although specific reactions of proteins of animal origin among themselves occurred only exceptionally, apart from immunological ones. With the elaboration of 'crossing electrophoresis' developed in our laboratory², search was made for plant proteins specific for animal proteins in the extracts of some beans. In Fig. 1 is shown an example of 'crossing diagrams of human serum' against the extract of jack beans. From Fig. 1 it is clearly shown that the extract of jack beans contained a protein which reacted specifically with serum proteins. This specific protein, named provisionally protein *J*, migrated toward the cathode under the usual conditions of electrophoresis of serum at pH 8.6. It reacted with α_1 -, α_2 -, β -globulins and probably also with γ -globulin, but not with albumin.

That the peaks of the crossing diagram, especially those corresponding to α_1 , α_2 -, and β -globulins, consist of precipitate could be clearly shown by two-

Fig. 1. Crossing diagram of human serum against protein *J* of jack bean. First electrophoresis: 0.003 ml./cm. of human serum was applied on lines *AB* and the first electrophoresis was carried out at 80 V. for 14 hr. Second electrophoresis: after the first one, 0.003 ml./cm. of water extract (5:1) of jack bean meal was applied on the line *XY* and the second electrophoresis was carried out at 120 V. for 8 hr. Barbiturate buffer, pH 8.6 and ionic strength, 0.05. Filter paper, Tōyō No. 52. Stained with amido-black 10 B

Fig. 2. Lines of precipitate appeared in the agar gel by the reaction of jack bean extract with animal proteins. *J*, Water extract of jack bean meal (5:1); *H*, human serum; *G*, guinea pig serum; *B*, bovine serum; *R*, rat serum; *S*, sheep serum; *P*, hog serum; *F*, fowl serum; *W1*, egg white diluted with 4 vol. of physiological saline solution; *W2*, egg white diluted eight times; *Y*, egg yolk diluted four times

dimensional crossing electrophoresis in agar gel, as the thin film of gel was transparent. The precipitation could also be observed by Ouchterlony's method³ as shown in Fig. 2.

As might be expected, the crossing diagrams of the sera of various animals showed species specificity, and human sera in some diseases showed distinct changes in pattern. Thus it is hoped to utilize the crossing diagrams of the sera against protein *J* for the diagnosis of certain diseases.

Further, protein *J* reacted with proteins of egg white as well as egg yolk. On the other hand, of the legumes hitherto tested, namely, kidney bean (*uzura* bean, *Phaseolus vulgaris* Linn.), 'torokusun' bean (a variety of the former), adzuki bean (*Adzuki angularis* Ohwi), cow-pea (sasage-bean, *Vigna sinensis* Savi), soy bean, and peanut, it was found that the kidney bean and 'torokusun' bean contained a similar protein, but their content was much smaller. From the crossing diagrams, it was found that they migrated toward the cathode with nearly the same mobility as protein *J* of jack bean and reacted chiefly with α_2 -globulin of serum. It is suspected that they are of the same nature and that such proteins might be distributed fairly widely in legumes.

Detailed reports on the species specificity of the crossing diagrams of sera of various animals and the changes in diseases will be published elsewhere.

Inositol Phosphatide in Peas

SOME properties and analytical data concerning an inositol phosphatide of peas have been reported previously^{1,2}. The availability of accurate methods for the determination of inositol in lipids, both by microbiological³ and chemical means^{4,5}, has made it possible to conduct further experiments which are reported here.

The quantity of inositol phosphatide fraction obtained by Wagenknecht's modification of Carter's procedure⁶ has been reported to increase during storage of raw peas (*Pisum sativum*) at -17.8°C . for periods of several days to several months². Since this inositol phosphatide fraction is known to contain impurities it was thought desirable to determine whether the percentage of inositol in the fractions was constant with time over the entire period of frozen storage. Aliquots of the inositol phosphatide fractions obtained from peas of Pluperfect variety were subjected to hydrolysis with 4N hydrochloric acid in sealed tubes at 120°C . for 16 hr. A modification of the periodate oxidation methods of Agranoff *et al.*⁵ and Le Baron *et al.*⁴ was used to determine inositol content of the hydrolysates. The results (Table 1) indicate that the percentage of inositol in these samples varies with time at -17.8°C ., but the total weight of inositol in the fractions is relatively invariant over the period from two days to four months of storage.

Table 1. INOSITOL CONTENT OF PEA INOSITOL PHOSPHATIDE FRACTIONS

Duration of frozen storage	Inositol* (per cent)	Inositol phosphatide (mgm.)	Inositol content (mgm.)
0 days	6.4	23	1.5
2 days	1.8	133	2.5
2 months	1.0	229	2.3
4 months	1.0	241	2.4
6 months	1.1	169	1.8

* Determined by modified periodate oxidation procedure (refs. 2, 4 and 5).

An enzymatic liberation of components of the inositol phosphatide fraction had previously been postulated, based on the observation that the inositol phosphatide content of raw (but not of heat-treated) peas increased with time². On the basis of the results presented here it would appear that this increase is caused by the enzymatic liberation, during frozen storage, of inositol-free lipid materials the solubility properties of which are sufficiently similar to those of phosphatidyl inositol to allow them to be extracted with the inositol phosphatide fraction.

Although several components were known to be present in the inositol phosphatide fraction, as was shown by chromatographic methods², previous paper chromatographic results gave no evidence for the presence of free inositol. As a further check on the absence of free inositol a sample of the water-soluble intact potassium form, which had been prepared from the calcium-magnesium mixed salt as described in a previous publication¹, was analysed for inositol by the excellent microbiological assay of McKibbin³, utilizing *Saccharomyces carlsbergensis* strain 4228. The purified potassium salt of the inositol phosphatide fraction was shown to contain less than 1 μgm . of free inositol per milligram.

Paper chromatographic evidence from another laboratory (Benson, A. A., personal communication) indicated that the calcium-magnesium mixed salts of pea inositol phosphatide contained, besides monophosphoinositide, components possessing the

R_F values of glycerophosphorylglycerol, phosphatidyl ethanolamine, phosphatidic acid, and some free inositol. The results presented here confirm that the purified potassium salt of the inositol phosphatide fraction contains inositol only in the bound form.

5-Deoxycytidylic Acid-deaminating Activity in Human Gastric Mucosa and Other Adult Mammalian Tissues

THE enzymatic deamination of deoxycytidylic acid to deoxyuridylic acid in sea urchin eggs and embryos has been demonstrated by Scarano¹ and Scarano and Maggio². Moreover, later results obtained by Scarano and Tallarico³ on the presence of deoxycytidylic acid-deaminase in livers of rat, chicken, rabbit in various stages of their embryonic development may indicate that this enzymatic activity, in developing or regenerating tissues, is proportional to their growth-rate. This latter view was confirmed in experiments by Maley and Maley⁴ on the determination of this enzymatic activity in embryonic tissues, in some spontaneous and experimental tumours and in regenerating livers.

In order to ascertain whether deoxycytidylic acid-deaminase is only characteristic of tissues in evolution or is common to tissues in continuous physiological regeneration, we examined several adult mammalian tissues for this enzyme activity. The tissues and organs investigated have been chosen in view of their active cellular proliferation.

The experimental procedure was essentially that proposed by Scarano¹. The homogenates were prepared by scrapping of the mucosa surface. The specific activity is referred to as μmoles of deoxycytidylic acid deaminated in 10 min. per 10 mgm. nitrogen of the homogenate (the deamination of 1 μmole of deoxycytidylic acid giving a ΔA_{280} of -0.344). The human tissues used for the enzymatic assays were collected immediately from surgical operations. Histological examinations were carried out on each of the specimens used.

The results obtained for the human gastro-enteric mucosa and for other mammalian tissues are reported in Table 1.

The results indicate that the rabbit gastric mucosa has a deoxycytidylic acid-deaminating activity although in a lesser amount as compared to the human. This enzymatic activity is not found in other segments of rabbit gastro-enteric mucosa and in testicle, being scarcely detectable in bone marrow. Cat and ox gastric mucosa have also been examined, and a very low deoxycytidylic acid-deaminating activity was found.

Table 1. 5-DEOXYCYTIDYLIC ACID-DEAMINATING ACTIVITY OF ADULT MAMMALIAN TISSUES

Human stomach	11.05 ± 0.75 μ mole/10 mgm. N per 10 min.		
" ileum	6.66	"	"
" colon	10.67	"	"
" sigmoid colon	4.48	"	"
" rectum	4.39	"	"
Rabbit stomach	1.57	"	"
" ileum	not detectable	"	"
" colon	not detectable	"	"
" testicle	not detectable	"	"
" bone marrow	scarcely detectable	"	"
Cat stomach	scarcely detectable	"	"
" ileum	not detectable	"	"
" colon	not detectable	"	"
Ox omasum	scarcely detectable	"	"

The failure to detect deoxycytidyllic acid-deaminase in some tissues, as in the case of the bone marrow and testicle, does not mean that the enzyme is completely absent. The enzyme might either have been destroyed during the extraction, or be present in too small a concentration to be detected with our assays.

Chromatographic analysis of the deproteinized incubation mixtures confirmed the formation of deoxyuridylic acid in agreement with the spectrophotometric results.

Further investigations, now in progress, indicate the presence of deoxycytidyllic acid-deaminase in human blood cells.

Serotonin in Pineapple

SEVERAL investigators have noted and studied the presence of serotonin and its precursors in fruit, mainly banana and tomato¹⁻⁴. As well as aiding the study of serotonin itself, this has the purpose of warning against the possible misdiagnosis of malignant carcinoid tumours by analysis of urine for elevated 5-hydroxyindoleacetic acid-levels when these are spuriously high following a diet rich in serotonin or its precursors.

During work on urinary 5-hydroxyindoleacetic acid, I noted unusually high peaks of excretion following the ingestion of pineapple juice. A more systematic study was conducted to determine the serotonin content of canned and fresh pineapple juice. Three brands of canned pineapple juice were selected, and samples were taken directly from the cans after shaking well. The fresh fruit was peeled and the skin discarded. The rest was pulped in a vitamizer and stored at about -7° C. The pulp was centrifuged and the supernatant used for analysis. Analysis was by the colorimetric method of Udenfriend *et al.*⁵.

The three brands of canned juice contained 23 mgm. serotonin/l., 25 mgm. serotonin/l. and 25 mgm. serotonin/l. respectively and the fresh juice 12 mgm. serotonin/l. It is almost certain that serotonin exists in the free state in the fresh as well as in the canned juice. The smaller quantity in the fresh juice may be due both to the rather inefficient

pulping method used compared with commercial juice extraction and to the possibility that canned juice is concentrated somewhat in the processing.

A study of the urinary excretion of 5-hydroxyindoleacetic acid following ingestion of pineapple juice was also carried out. Two adult male subjects each drank 500 ml. of commercial canned pineapple juice and gave urine samples over the following 6 hr. The samples were analysed for 5-hydroxyindoleacetic acid by the colorimetric method of Udenfriend *et al.*⁶. The method was slightly modified at the final stage, the ethyl acetate being saturated with water at room temperature immediately before use. This ensured that the final volume of aqueous phase was the same, regardless of the atmospheric temperature. Table 1 shows the pattern of excretion.

Table 1

Subject 1	μ gm./min. 5-hydroxyindoleacetic acid
Time	1.8
7.15-10.30	Pineapple ingested
10.30-11.45	22.1
11.45-12.50	31.2
12.50-2.15	18.0
2.15-3.15	7.7
3.15-4.45	5.9
Subject 2	3.0
7.45-10.30	Pineapple ingested
10.30-11.20	8.6
11.20-12.25	30.5
12.25-1.30	17.7
1.30-3.00	9.8
3.00-4.40	3.7

The rate of excretion per hour over this period has increased by approximately ten times.

It would seem, therefore, that pineapple can be added to the list of forbidden fruit in a diet where 5-hydroxyindoleacetic acid analyses are being conducted and may also open another avenue to the study of serotonin.

I wish to acknowledge the help of Mr. R. Horgan with the colorimetric procedures.

Nitrite Oxidation by *Nitrobacter* in the Presence of Certain Nitrophenols

It was reported by Simpson¹ that 2,4-dinitrophenol, at a concentration of 1 mM, strongly inhibits nitrite oxidation by *Nitrobacter*, although compounds such as ethyl nitrite and nitromethane appeared to have no inhibitory action. Other workers² have, however, failed to obtain any inhibition with 2,4-dinitrophenol. We have therefore re-investigated the effect of this compound on nitrite oxidation.

The oxidation of nitrite, at an initial concentration of 10 mM, by washed suspensions of *Nitrobacter* was followed manometrically at 30° in the absence of 2,4-dinitrophenol and in the presence of varying concentrations of the compound. All experiments were performed in the presence of 0.05 M phosphate buffer pH 7.5 and the solution of 2,4-dinitrophenol

used was prepared in this buffer. It was found that the compound is a powerful inhibitor of nitrite oxidation and the inhibition produced by different concentrations is shown in Table 1.

Concentration of 2,4-dinitrophenol (mM)	Percentage inhibition of oxygen uptake
0.8	16
0.6	23
1.2	64
1.8	80
2.4	94

One possible explanation of the effect of 2,4-dinitrophenol is that, by virtue of its nitro groups, it can compete with nitrite for the nitrite-oxidizing enzyme. However, it was found that variation of the initial nitrite concentration between 6 and 44 mM had little effect on the degree of inhibition produced by a given concentration of 2,4-dinitrophenol. It therefore seems unlikely that such a competition between nitrite and 2,4-dinitrophenol occurs.

Another possibility is that 2,4-dinitrophenol inhibits because of its well-known ability to uncouple oxidative phosphorylation³. Although it has yet to be proved, it is almost certain that nitrite oxidation by *Nitrobacter* is linked to the production of high-energy phosphate bonds. If this phosphorylation is coupled in an obligatory way, then any uncoupling agent should inhibit nitrite oxidation. The effect on nitrite oxidation of two dyes, janus green and brilliant cresyl blue, both of which have been shown to uncouple oxidative phosphorylation in mammalian systems⁴, was therefore tested, but neither had any effect at concentrations up to 10 mM. It is possible, however, that neither dye could penetrate to the site of nitrite oxidation within the cell.

The effect on nitrite oxidation of a few compounds related to 2,4-dinitrophenol was also tested, and the results are given in Table 2. All conditions were the same as in the experiments with 2,4-dinitrophenol; each compound was used at a concentration of 1 mM.

Table 2. EFFECT ON NITRITE OXIDATION OF SOME COMPOUNDS RELATED TO 2,4-DINITROPHENOL

Compound tested	Percentage inhibition of oxygen uptake
2,5-Dinitrophenol	61
m-Nitrophenol	77
p-Nitrophenol	100
p-Nitroaniline	25
Phenol	7

It is of interest that the nitrophenols produced the greatest inhibition, and it appears that both the phenolic hydroxyl and nitro groups are necessary to give the maximum effect. As in the case of 2,4-dinitrophenol, inhibition may be due to a direct action on the nitrite oxidizing enzyme, or to an uncoupling of oxidative phosphorylation.

PHYSIOLOGY

Inhibition of Appetite in Dairy Cattle by Certain Intermediate Metabolites

MANNING *et al.*¹ have discussed the applicability of the glucostatic theory of Mayer *et al.*² to the regulation of food intake in sheep. Glucose in ruminant animals plays a relatively minor part in energy metabolism, since a major portion of ingested carbohydrates are degraded to volatile fatty acids which are absorbed into the blood stream via the rumen wall³. Consequently, a chemoreceptor mechanism of regulation of intake in ruminants may depend on any of several metabolites. The objective of this experiment was to examine several major intermediate metabolites for their effect on appetite.

Sodium acetate (adjusted with acetic acid to pH 7), glucose, acetic, propionic, valeric, hexanoic and lactic acids were administered intravenously by constant drip over the same 8-hr. period during each of three consecutive days. In each trial, identical twin cows of the Guernsey, Holstein-Friesian or Jersey breed were injected. One twin received the metabolite in three litres of physiological saline and the other received an equal amount of physiological saline. The injections were made into the jugular vein through a small polyethylene catheter inserted previously that remained in place throughout each trial. The catheter was firmly attached to the shoulder of the animal, thus allowing all manipulations to be made at that position. This technique permitted the elimination of any restraining apparatus other than a halter, to which the animals were already accustomed. The injection procedure and experimental manipulation apparently did not affect intake, since the control twins consumed the same amount of feed during the three-day injection period as they did during the three days prior to injection. The effect on appetite was determined by comparing the voluntary hay intake of chopped alfalfa of the control twin (saline injected) with that of the treatment twin (metabolite injected). The relative amounts of each metabolite administered are shown in Table 1. These amounts are expressed as a percentage of body maintenance requirement⁴. So far as possible, the higher levels of organic acids used were those corresponding to what would seem to be equal to, or in excess of, the actual amounts absorbed from the gastro-intestinal tract during an 8-hr. period.

Administration of glucose did not elicit a reduction in daily intake. This is in agreement with the observation of Vallance and McClymont⁵ during injection of 4 kgm. of glucose over a 48-hr. period, and that of Manning *et al.*¹ following intravenous administration of 50 per cent glucose to sheep. In the case of the higher (25 per cent) level, concentrations of blood glucose were raised from approximately 40 mgm. per 100 ml. to approximately 100 mgm. per 100 ml., or about 2½ times normal. From these results, it is clear that raised levels of blood glucose have little or no effect on the appetite of dairy cattle.

The administration of the higher level of acetic acid and sodium acetate resulted in a highly significant reduction in feed intake during the 8-hr. injection period; with both metabolites consumption was negligible. Consumption during the other 16 hr. of the three injection days approached normal. However, the 24-hr. feed-intake values during the three days were significantly lower for the treatment

Table 1. EFFECT OF INTRAVENOUSLY ADMINISTERED METABOLITES ON CONSUMPTION OF FEED BY IDENTICAL TWIN COWS

Metabolite	Level*	No. of trials	Average intake during 8-hr. injection period, 8 days.		Average 24-hr. intake including 8-hr. injection period, 8 days.	
			Treated twin (lb.)	Control twin (lb.)	Treated twin (lb.)	Control twin (lb.)
Glucose	4 0	2	8 2	9 2	10 5	18 8
Glucose	25 0	2	5 8	6 4	16 4	15 8
Sodium acetate	12 5	2	0 5§	8 4	14 0†	20 2
Acetic acid	12 5	1	0 8§	6 3	3 1†	17 9
Acetic acid	4 0	1	14 8	14 1	27 1	28 6
Acetic acid	8 5	1	6 8	9 8	18 1	16 6

twins than for the control twins. Administration of propionic acid resulted in significant reductions in intake during the 8-hr. and 24-hr. periods. There was very little carry-over effect from acetate, acetic or propionic acid injections, since eating began very soon after cessation of each 8-hr. injection period.

None of the other metabolites mentioned above caused a significant reduction in feed intake. Valeric acid and lactic acid injection resulted in a small mean reduction in intake, but the results were variable and exhibited no definite trend.

The results of this series of trials strongly suggest the existence of a chemoreceptor response to changes in blood constituents. Apparently, one of the possible mechanisms of regulation of intake involves the absorption of acetic acid and propionic acid or, as indicated by the experiment using sodium acetate, the acetate and propionate ions, into the blood stream which, at threshold-levels, would elicit a chemoreceptor response inhibiting intake. Acetic and propionic acid inhibition of feed intake may account for the observation that dairy cattle consume less forage in the form of silage than in the form of hay, since silage contains significant amounts of these acids.

The level of feed consumption (highly variable in ruminants) is of the utmost importance, since gross efficiency of milk production is limited by voluntary intake of nutrients. From the results of this experiment, it is postulated that rations tending to promote the production of metabolites serving as energy sources that do not inhibit nutrient consumption could greatly enhance the gross efficiency of animal production by promoting an increase in voluntary intake of nutrients.

Electrical Inexcitability of the Synaptic Membrane in the Frog Skeletal Muscle Fibre

VARIOUS types of evidence indicate that the endplate potential of frog twitch muscle fibres is an electrically inexcitable synaptic activity^{1,2}. Electrical inexcitability of the synaptic membrane has been demonstrated most clearly in cells in which electrically excitable activity is lacking, for example, the electroplaques of marine electric fishes³ and slow muscle fibres of frog⁴. Electrical inexcitability of synaptic membranes in other cells has also been demonstrated^{1,2}. Hitherto, however, it has not been shown that the chemically excitable⁵ synaptic membrane of twitch muscle fibres is also unresponsive to electrical stimuli. The junctional region is small, and there is intermingling of membrane of greater and lesser chemical sensitivity⁶.

Experiments described here demonstrate that sites of the junctional membrane do not develop an inward current when a directly evoked spike is propagated through the endplate region. These are also the sites with the largest and most rapidly rising externally recorded spontaneous miniature endplate potentials.

Most of the work was done on whole sartorius muscles of frog (*Rana pipiens*). A few experiments were performed on isolated single nerve-muscle fibre preparations from the semitendinosus muscle, the results being identical in both series. The preparations were bathed in hypertonic saline, made by doubling the sodium chloride of a standard frog Ringer's solution. Hypertonicity served two functions: decreasing the contraction of the muscle⁶ and increasing the frequency of spontaneous miniature endplate potentials⁷. The latter effect aided location of synaptic sites, which appear to be distributed as small patches in the junctional region⁸.

Superficial nerve endings to a neuromuscular junction were visualized, and a recording micro-electrode was inserted into this region of the muscle fibre. Spikes were elicited by depolarizing pulses which were applied through another intracellular electrode in the same muscle fibre at some distance away from the junction. An external recording micro-electrode was used to explore the endplate region for discrete areas of spontaneous sharply rising external negativities. The potentials were recorded with direct coupled amplifiers.

When the external micro-electrode was localized at a site which yielded rapidly rising outside-negative miniature endplate potentials, the potential recorded during the spike was purely positive (Fig. 1A). On moving the micro-electrode in the long axis of the fibre less than 5 μ from this site a brief dip developed in the positivity (Fig. 1B). The dip became larger when the electrode was moved slightly farther away (Fig. 1C). Negativity developed on moving the electrode another 30 μ (Fig. 1D). Further displacement of the electrode by about 100 μ resulted in a potential with a very large negativity (Fig. 1E). This last was the potential usually recorded outside the muscle fibre at non-synaptic regions.

Invasion of the junctional region by the directly evoked spike was confirmed by the records obtained with the intracellular micro-electrode (Fig. 1F). The externally probed site which gave the purely positive potential of Fig. 1A was shown to give rise to spontaneous negativities both before and after the spikes

Fig. 1. Potentials at different sites outside endplate of single semitendinosus muscle fibre (*R. pipiens*) during passage of directly evoked spike. Latter is shown (F) as recorded intracellularly at endplate region with low amplification and simultaneously at gain used for extracellular recordings (A-E). The spikes were elicited by long, weak intracellular depolarization, to minimize stimulus artefact. Accordingly, latency varied in different records. A, positivity recorded at endplate site which also yielded maximal, steeply rising, externally negative miniature end-plate potentials B-E, changes produced on moving external micro-electrode away from this site, as described in text. Amplitudes in different records cannot be compared, since they depend on closeness of micro-electrode to surface of membrane. Records retouched

were elicited, thus demonstrating the undamaged state of the recording site. Large negativities associated with spikes were never recorded from sites producing rapidly rising miniature end-plate potentials. At non-junctional regions external positivities were seen only in grossly damaged fibres.

The potential recorded by a closely placed external electrode is proportional to the membrane current⁸, a negative potential indicating inward current and activity of the region probed by an external micro-electrode. Thus, the purely positive potentials recorded at restricted sites of the synaptic region indicate that these sites remained inactive during passage of the impulse while sites less than 100 μ away were excited by the initial outward depolarizing local circuit current and gave rise to large external negativity. The brief dips in the positivity recorded at intermediate sites reflect the distribution of current flows in regions near both active and inactive membranes.

The same regions that are inactive during passage of a spike are capable, however, of becoming active, passing an inward current and generating the externally negative miniature end-plate potentials. The regions in which the external miniature end-plate potentials are largest and steeply rising are also the sites which are most sensitive to ionophoretic applications of acetylcholine⁴. It may be reasonably concluded, therefore, that the sites of the junctional membrane which generate miniature end-plate potentials and which respond by depolarization to chemical excitants are also the neurally excitable synaptic sites of the neuromuscular junction. They are electrically inexcitable, at least by stimuli representing a change in membrane potential of more than 120 mV., the spike amplitude of the muscle fibre.

Absorption and Excretion of Copper in Mice

THE marked elevation of tissue copper that occurs in Wilson's disease is generally thought to be due to an increased absorption of copper from the gastrointestinal tract^{1,2}. In the work reported here, this concept was re-examined.

Swiss albino mice, 5-7 weeks of age, were kept on a diet providing 45-75 μ gm. copper a day per mouse. Various amounts of copper, to which copper-64 was added, were then given orally or intravenously. Intravenous injections were given in a 3-5 sec. period; in oral administration, 0.2 ml. of the copper solution was passed into the stomach through a polyethylene catheter. Three mice from each group given a specific copper dose were bled at intervals for organ and serum radiocopper assays and at least 5 mice were used for collection of urine and faeces.

Fig. 1. Cumulative faecal and urinary excretion of a copper dose after intravenous injection. $\circ$, 1.7 μ gm.; $\bullet$, 6.3 μ gm.; Δ , 11 μ gm.; $\blacktriangle$, 15.5 μ gm.; $\square$, 25 μ gm.; $\blacksquare$, 48 μ gm.

The faecal excretion of a copper dose after intravenous injection of amounts from 1.7 μ gm. to 48 μ gm. is shown in Fig. 1. The larger the dose of copper given, the greater was the amount of copper excreted; 96 μ gm. injected under these conditions was lethal to half the mice within 1 hr. Since, after intravenous administration, copper appears in faeces principally through biliary excretion³, it would seem that the amount of copper excreted in bile by the normal animal increases with increasing copper loads. In accord with this, following the injection of 0.15, 1.1, 3.2, 11 and 48 μ gm. copper, at least 0.05, 0.63, 1.7, 6.7 and 15 μ gm. respectively were found in the liver 10 min.-7 hr. after administration; hepatic

Fig. 2. Absorption of copper after oral administration (●). Dashed line passing through origin and parallel to absorption curve at doses of 25 μgm. or more represents hypothetical first-order process; ○, total absorption curve less the first-order absorption process.

radiocopper then decreased and was afterwards found in the faeces. The concentration of copper in several bile samples obtained from animals killed 21 hr. after injection was found to increase with the size of the dose. In contrast, the concentration of copper in bile in Wilson's disease is in the normal range despite the presence of a markedly increased hepatic copper pool³.

When mice were given 46 μgm. copper intravenously once a day for 6 days, the faecal excretion of the last dose was similar to that of the first dose. Since only part of each dose was excreted before injection of the next, all preceding doses added to the total copper excretion. Thus, even with continued copper administration, the larger the copper load, the greater was the faecal copper excretion.

With intravenous doses of copper of 0.15–11 μgm., only a small fraction of the dose appeared in the urine (Fig. 1). With 48 μgm., almost 30 per cent of the dose was excreted within 90 min.

The maximum amount of copper present in the body at one time represented the minimum amount of copper absorbed, and was estimated by subtracting the radiocopper present in the gastrointestinal contents from that in the total body. The results are shown in Fig. 2. It can be seen that the larger the dose the greater was the amount of copper absorbed. There appeared to be at least two processes involved in absorption: one appeared to be first-order and the other suggested an enzymatic mechanism.

When mice were injected with 46 μgm. stable copper intravenously or 92 μgm. stable copper subcutaneously once a day for 6 days prior to the oral administration of 1.7 μgm. labelled copper, the absorption of labelled copper was 75 and 58 per cent of normal, respectively. This finding is the converse of that found in Wilson's disease and is in accord with a dilution of the oral copper in the copper excreted into the intestinal tract from the injected load.

The results presented in this communication suggest that the elevation of tissue copper in Wilson's disease

is probably due to a defect in biliary copper excretion rather than an increase in copper absorption.

Growth of Mouse Femurs during Continual Centrifugation

THE size and shape of various parts of an organism are believed to be influenced by gravity¹. One would expect the relative size and cross-section of supporting structures to increase with either an individual's height or the intensity of the environmental gravity.

Gray and Edwards first experimentally demonstrated such a gravitational influence on the cross-section shape of a growing structure by continual centrifugation of wheat coleoptiles². Smith and his co-workers found that this would increase the size of chicken legs³. This report deals with the greater size and altered shape of mouse femurs.

This is one aspect of a long-range programme designed to study the influence of gravity on development. In this particular work, the *NLW* strain of five-week-old white mice were exposed to continual centrifugation at four times the Earth's gravity (4g). Duration of exposure was for periods of 1–8 weeks. The diet consisted of 'Purina' laboratory chow for mice and uncooked potatoes. These potatoes served as the only source of water. The centrifuge is described elsewhere⁴. A number of anatomical and physiological measurements were performed at the termination of exposure. The details of these determinations will be described later. The effect on the femurs of female mice was more striking than many other effects.

As can be seen from Fig. 1, experimental animals first lost mass and then continued to grow. At the end of one week they had returned to approximately initial body mass. The femurs, on the other hand, continued to grow just as fast, if not faster, than the controls. At later developmental stages, this rapid growth of experimental bones is not as pronounced. The femurs also assumed a more circular cross-section. Other factors being equal, such a change would give a supporting structure more strength with which to support gravity.

There are at least two possible explanations for the faster bone growth as compared to total experimental growth: mechanical stress and moderate starvation. Wolff's law proposes that mechanical force will evoke growth of the stressed portion of the bone⁵. The artificial increase in the force of weight during centrifugation could certainly cause such stresses. The initial decrease in body mass can be largely attributed to a lowered food consumption during the first week of centrifugation. In cases of moderate starvation, bone developmental responses demonstrate a lag, being in most cases among the last organs to show growth retardation⁶. Further work

Fig. 1 Growth of various structures of the female white mouse during centrifugation at 4g. The experimental points at one week and eight weeks of exposure represent determinations with nine and seven animals respectively. These animals were killed at the appropriate time. Body masses at zero time are based on the averages for these 16 animals. Other values from zero time were for five mice which were killed at five weeks of age. Control values are from individual litter mates of the experimental animals. These animals grew in cages identical to those placed in the centrifuge. The index for shape of the femur cross-section is calculated by dividing the shorter thickness (depth) by the greater thickness (width). Solid lines are for control curves and broken lines for experimental curves. Standard errors are indicated by the extent of the vertical lines above or below the experimental points. When these errors are not shown for the animals at two and four weeks it is because results are based on less than three measurements. In other cases the extent of the error is less than the extent of the points.

is necessary to demonstrate the actual cause or causes for the relative increase in size of femur. Starvation alone does not seem a very plausible explanation for change in cross-section. The shorter axis of the bone shaft, being mechanically weaker, should be the most susceptible to a growth-enhancing stress, thus producing greater roundness.

This investigation was supported by a grant from the U.S. Public Health Service.

Evidence of a Specific Action on the Central Nervous System by the Esters of Some Plant Growth Regulator Acids

THE pharmacology of plant-growth regulator acids has been little studied; nevertheless, these substances which react in minute traces in green plants possess intense biological activity. We have prepared

various esters of these acids with the intention of studying their action on the central nervous system. Dimethylaminoethanol was chosen as the agent of esterification because Pfeiffer *et al.*¹ had demonstrated that this amino-alcohol has stimulating effects. We have synthesized the dimethylaminoethylic esters of the following acids: phenoxyacetic acid and some of its derivatives substituted on the aromatic nucleus (4-chloro-, 4-fluoro-, 2,4-dichloro-, 2-methyl-4-chloro-compounds), naphthalenic acid, α - and β -naphthoxyacetic acid, 3-indolyacetic acid, phenylpropionic acid.

The method of preparation and the physical constants of these products have already been described².

Pharmacological study of these different substances has shown that they possessed a specific action on the central nervous system, principally at the level of the hypothalamus³; this property is not due exclusively to dimethylaminoethanol since it can be substituted by other amino-alcohols; but on the other hand the acidic group seems to be the important part of the molecule. Among the compounds studied, the dimethylaminoethylic ester of *para*-chlorophenoxyacetic acid (which we term 235 ANP) was particularly active.

The oral *L.D.*50 of 235 ANP is 1,750 mgm./kgm. Rats treated chronically at 400 mgm./kgm. a day during three months and longer tolerate this dose without any blood, hepatic or renal troubles.

(a) The specific action on the central nervous system was shown in the following experiments:

Fish (*Cyprinus vulgaris*, *Phoxinus phoxinus* Linné) immersed in a 0.5/1,000 solution of the 235 ANP in water exhibit convulsive seizures and dilation of chromatophores. The Siamese fighting fish, even in the absence of a male congener, develops its fins, expands its chromatophores, and attains a fighting temperament.

In mice, autographic records showed that after administering 150 mgm./kgm. subcutaneously of 235 ANP for ten days a significant increase in spontaneous activity could be observed.

In the rabbit, 100 mgm./kgm. of 235 ANP injected intravenously significantly lowered the threshold for seizures from intravenously infused metrazol.

(b) The specific effect of 235 ANP on the hypothalamus was demonstrated with the help of B. Minz's method⁴.

It is known that the application of a piece of filter paper of 5 mm.², steeped in adrenaline solution (5/100), on the fronto-parietal cortex of a female rabbit causes arterial hypertension and uterine contractions, due to the secretion of hypertensive and oxytocic substances by the hypothalamus⁵.

The same reactions occur in a hypophysectomized animal; but they are suppressed if the hypothalamus is destroyed⁶.

We have confirmed the correctness of this method, which permits us to study the effect of psychotropic drugs on the hypothalamus⁷.

We have observed that the 235 ANP provokes a considerable stimulation of the hypothalamic area (Fig. 1).

The other compounds, derived from plant-growth regulator acids which were prepared, are still being studied; so far we have already examined the effect of the substances on the chromatophores of fish, on glycaemic regulation and their relationship with catecholamines and serotonin.

Already the results achieved suggest research on the manner in which the esters of plant-growth

Fig. 1. Blood pressure record. A, Application of adrenaline on the fronto-parietal cortex of a rabbit. After intravenous injection of 235 ANP (60 mgm/kgm) one can observe a considerable increase of the hypertensive reaction.

regulator acids exert their stimulation. So far three possibilities have been examined.

(a) The potentialization of the central action of adrenaline by a stimulation of the cerebral cortex induced by the drug. (b) Direct action on the hypothalamus and hypophysis or on the level of catecholamines and serotonin, which are found in great quantities in this region. (c) Regularization by 235 ANP of the metabolic activity of the hypothalamic region could explain some of the powerful actions of the drug.

Pharmacological and biochemical studies are now being carried out with the view of explaining the mechanism of action of 235 ANP and other esters of plant-growth regulator acids, which seem to act as metabolic regulators at the level of the hypophyseal-hypothalamic region.

HÆMATOLOGY

Glutathione Stability Test in Hæmoglobin E - Thalassaemia Disease

HÆMOGLOBIN E - thalassaemia disease represents a double heterozygous state with reference to genes for hæmoglobin E and thalassaemia. Studies on glutathione stability which have recently provided valuable information regarding the cause of hæmolysis as it occurs in drug-induced hæmolytic anæmia and in hereditary non-spherocytic hæmolytic anæmia have not so far been done in hæmoglobin E - thalassaemia disease. In the present communication, 20 cases of hæmoglobin E - thalassaemia disease were investigated with reference to the behaviour of their erythrocytically reduced glutathione-level when incu-

Table 1. RELEVANT FEATURES OF TWENTY CASES OF HÆMOGLOBIN E - THALASSAEMIA DISEASE

	Mean	Range
Age (yr.)	5.8	1-28
Hæmoglobin (gm. per cent)	6.44	3.4-9.28
Hæmoglobin E (per cent)	23.8	13.0-60.0
Reticulocytes (per cent)	8.1	2.1-17.0

bated *in vitro* with acetylphenylhydrazine. The relevant features of these 20 cases are given in Table 1.

The method employed was essentially the same as originally evolved by Beutler¹. In order to increase the sensitivity of the test, 4 mgm. of glucose was added to 1 ml. of blood as suggested by Szeinberg *et al.*² and later adopted by Beutler³. With this method, the range of reduced glutathione destruction in the normal Bengalee population varied from 1 to 10 mgm. per 100 ml. of erythrocytes. Two apparently normal persons, however, showed unstable glutathione-level, indicating that a certain proportion of Indians has such glutathione instability similar to the state of instability reported first in people of negroid origin^{4,5} and later in those of Syrian, Iranian and Jewish⁶ extraction. In contrast to the normal findings, the pattern in hæmoglobin E - thalassaemia disease was different (Table 2). In 12 out of 20 cases, the glutathione destruction exceeded 30 mgm. per 100 ml. of erythrocytes and in 9 the post-incubation level was lower than 30 mgm. In all the patients, both sensitive and non-sensitive, glucose-6-phosphate dehydrogenase activity of red cells was, however, found to be high.

Table 2. RESULTS OF GLUTATHIONE STABILITY TEST IN NORMALS AND IN HÆMOGLOBIN E - THALASSAEMIA DISEASE

	No. of subjects	Reduced glutathione-level in mgm. per 100 ml. of erythrocytes

Blood Groups of Selected Aboriginal and Indigenous Populations

THE Laboratory of Physical Anthropology at Yale is investigating the distribution of the following genetic traits in various populations of Primates, including man: the blood groups, the serum transferrins (β -globulins), haptoglobins, and hæmoglobin

variants. This is a report of the blood types in three of the human populations investigated.

(A) *Kapauku Papuans*. Seventy samples of venous blood were obtained from the inhabitants of the West Central Highlands of New Guinea. These people occupy an area between 135° 25' and 137° longitude and 3° 25' and 4° 10' south latitude. They are referred to as *Kapauku* by coastal inhabitants of Netherlands New Guinea and call themselves *Me*. The frequencies are reported in Table 1. The discovery of two Diego-positive individuals is not wholly unexpected for this area. It has not, however, been reported before. The frequencies of the ABO(H) blood types are different from those published for other Papuan groups by Sanger *et al.*¹ and Bijlmer²⁻⁴. No attempt was made to select a random sample, since our research is aimed at relating the social structure of aboriginal human groups to gene frequencies. Therefore, blood samples are taken, when possible, from individuals that are related to one another by some network of social relations. Thus, the fact that the ABO(H) frequencies differ radically from others reported from Papua, particularly in the unusually low frequency of type A, may be due to our deliberate attempt to select related individuals. However, the *Kapauku* are an isolated people, a factor which must be considered.

Table 1. KAPAUKU PAPUANS

A ₁	7	K+k+	1
O	52	K-k+	69

MN	17	CcDee	4
Fy ^a +	70	ccDee	1
U+	70	ccDee	1
P+	25	OwCDee	1
Kp ^b +	70		

Nijenhuis⁵ reports the presence of the Henshaw (He) antigen among Papuans. Fifty-one of our samples were tested with an He reagent. All were Henshaw-negative.

(B) *Indigenes of Providencia Isla, Colombia*. Providencia is an island off the coast of Colombia. Forty-two samples of venous blood were drawn and typed. The results are reported in Table 2. The population is a mixture of Indian, Negro and White. All C-positive bloods were C^w negative. Published frequencies of blood types from Colombia report only Indian populations, thus comparisons are not possible at present.

Table 2. INDIGENES OF PROVIDENCIA

A ₁	3	K+k+	1

P+	39	CcDee	1
Fy ^a -	42	ccDee	1
D ⁺ -	42		

(C) *East Africans*. One hundred and eighty-nine bloods from several Kenya tribes were tested. Table 3 reports the frequencies found in the entire group, which consisted of Masai, Wakamba, Luo, Kikuyu, Giriama and Pokomo tribesmen. The Masai samples were drawn at Kajiado Hospital, which serves the Masai tribe. The Wakamba samples were drawn at the village of Mlutui, near Kibwezi railroad station. The rest were drawn from patients at the George VI hospital in Nairobi and the Coast Province Hospital in Mombasa.

Table 3. EAST AFRICANS

Blood types	Wakamba	Masai	Coast tribes Pokomo, Giriama	Upland tribes Luo, Kikuyu
A ₁	7	17	7	2
A ₂	5	3	1	0
O	21	38	21	8
B	16	24	11	1
A ₁ B	0	0	1	0
A ₂ B	1	4	1	0
ccDee	37	62	27	8
CcDee	7	10	4	2
ccDee	5	9	7	0
ccDee	1	0	0	0
CcDee	0	1	0	0
CcDee	0	1	2	1
ccDee	0	2	0	0
CCDee	0	1	0	0
ccdee	0	0	2	0
M	14	37	11	3
N	8	10	9	4
MN	28	39	22	4
K-k+	50	86	40	11
K+k+	0	0	2	0
P+	48	84	40	9
P-	2	2	2	2
Fy ^a +	0	2	4	0
Fy ^a -	50	84	38	11
U+	50	86	42	11
D ⁺ -	50	86	42	11

The frequencies are generally similar to those reported by Foy *et al.*⁶ and Allison *et al.*⁷. The number of A₂B samples seems unusually high and cannot be explained by our non-random method of sampling. Each A₂B individual is clearly unrelated to the others. All C-positive bloods were tested and found to be C^w negative.

The co-operation of colleagues at the Nairobi Medical Research Laboratories, Dr. L. M. J. Couvee of Bialk, New Guinea, and Dr. Alvarao Garcia N. of San Andres, Colombia, is gratefully acknowledged. Dr. Fred Allen, Boston Blood Grouping Laboratory, provided the anti-Mg sera, and Dr. M. Layrisse of Caracas, Venezuela, provided the anti-D⁺ sera. This research is supported by RG 6053 of the United States Public Health Service, and was aided by the Wenner-Gren Foundation and United States Atomic Energy Commission Grant AT-(11-1)-405 to the University of Michigan.

Interrelations of Serum Protein Fractions in Normal Humans

RECENT advances in the study of protein-protein interactions¹, including the haptoglobin-haemoglobin² and protamine-fibrinogen³ complexes, have stimulated interest in serum protein abnormalities such as macroglobulin aggregation⁴. Although the serum proteins frequently undergo significant alterations with the onset of disease and yield characteristic patterns on electrophoretic separation, little is known about their interdependence in the healthy state. The present report describes an electrophoretic examination of interrelations between protein fractions in the course of variations within the normal human range.

Blood was obtained from 100 healthy persons between the ages of sixteen and seventy-two. There were equal numbers of males and females. Serum proteins were separated by cellulose acetate electrophoresis and stained with fastamine green. The dyed fractions were eluted, and the concentrations of albumin and α_1 -, α_2 -, β -, and γ -globulins then calculated by comparing the quantity of eluted dye with the known dye uptakes of standard preparations. Since for each sex the means between the corresponding fractions were not significantly different, the two groups were combined. Table 1 summarizes the results.

Table 1. MEANS AND STANDARD DEVIATIONS OF SERUM PROTEIN FRACTIONS OF 100 NORMAL PERSONS

	Albumin	α_1	Globulins		γ
		α_2	β		
Mean (gm/100 ml)	4.07	0.30	0.78	0.92	1.29
± Standard deviation	0.37	0.04	0.11	0.12	0.23

The five fractions were approximately normally distributed and, using standard statistical procedures, the partial correlation coefficients of the ten possible pairs were determined. Table 2 indicates that the most significant values were obtained for the pairs derived from the α_1 -, α_2 -, and β -globulins. It is noteworthy that the least significant values are those of pairs involving γ -globulin of reticulo-endothelial origin with the other proteins of hepatic origin.

Table 2. PARTIAL CORRELATION COEFFICIENTS OF NORMAL SERUM PROTEIN FRACTIONS

	α_1	α_2	Globulins		γ
			β		
Albumin	-0.183	-0.145	0.210	0.031	
α_1 -Globulin		0.987	0.317	0.087	
α_2 -Globulin			0.247	-0.046	
β -Globulin				0.029	

The virtually perfect correlation between α_1 - and α_2 -globulins is explicable in terms of similarity of constitution. Both fractions comprise glycoproteins and lipoproteins, and have sedimentation rates close to 3 Svedberg units⁵. Similarly, the α_1 -globulin- β -globulin correlation can be considered to result from the lipid moiety common to each; both sediment at 5 S⁶. The lower correlation between α_2 - and β -globulins may be attributable to the glycoproteins and lipoproteins contained in each. Both sediment in the ultracentrifuge at 7 and 12 S⁶.

The most significant negative correlation was found for albumin- α_1 -globulin. In this connexion Schultze⁷ has noted that some α_1 -globulin is carried by albumin under paper electrophoretic conditions, while Tata⁸ has demonstrated the existence of a prealbumin- α -globulin complex. Of interest is the present finding

that the albumin- γ -globulin relation is not inverse as it frequently is in disease. It is certain that the behaviour of some protein fractions as dependent variables is, like their distribution⁹, governed by experimental conditions.

PATHOLOGY

A New Factor in the Use of Antibiotics

New clinical problems have arisen from the intensive use of antibiotics during the past twenty years. During this time, several aspects of those problems have been studied in an attempt to elucidate the various mechanisms related to the sensibility, resistance and dependence of micro-organisms as well to the mode of action of antibiotics.

When observations are made, not *in vitro*, but in host organisms, the interpretation of the phenomenon becomes more confused due to the many variables taking part in the problem and to the effect of antimicrobial activity added to humoral defensive responses of the host against the pathogenic agent. In these responses, both the drug effect breaking down the equilibrium of normal phagocytic activity and the formation of antimicrobial antibodies are often found.

Irregularities in the activity of antibiotic suspensions have been observed by us between serum of patients having different levels of antibiotic and their specific antimicrobial activity, as well as when looking at the behaviour of bacteria against the antibiotics or their associations. Certain irregularities were found in associations of antibiotics of known *in vitro* bactericidal activity when this activity was greatly reduced *in vivo*, during treatment of the parasitized organism. In spite of adequate dosing, sera of various patients with analogous symptoms and under the same treatment showed differences in their antimicrobial activity, which could not be explained satisfactorily.

These abnormalities could not be easily explained either by differences of antibiotic absorption or by different physiological responses of the human body, either by sex or by age, constitution, etc. It becomes necessary to consider a very representative factor common to the characteristics of previous treatments.

These observations lead us to think of the existence of antagonistic substances, not natural, but of a circumstantial origin in the host organism and capable of being formed as a response to an external stimulus promoted by the drug.

According to this hypothesis, experiments were carried out with various antibiotics, 'Kanamycin' being the first studied. This substance was injected into rabbits through peritoneal and endovenous routes at regular intervals for one month. Doses were steadily increased from 10 to 200 mgm. At the end of each treatment, a total amount of 450 mgm./kgm. had been injected into each rabbit, 12 animals having been used in each lot. The doses of 'Kanamycin' used were not toxic to the rabbits.

Checks of anti-'Kanamycin' activity of normal fresh serum were provided, using samples of blood extracted by heart-puncture from the test animals in advance of their treatment.

The technique used for studying the anti-'Kanamycin' activity of sera was as follows: 0.2 ml. of rabbit serum was placed in small test-tubes of about 1.2 ml. capacity and another 0.2 ml. into 400 ml. solution of 'Kanamycin' was added. A series of two-fold dilutions followed until a 0.097 concentration of 'Kanamycin'/ml. was obtained. Therefore, concentrations of the antibiotic in the assay ranged from 200 to 0.097 γ . For each series a 'time of contact' was established (Fig. 1). Parallel tests using sera from untreated rabbits were performed for every series as control of normal sera activity. The series were finally completed—at the end of every conventional 'time of contact'—with 0.2 ml. of a bacterial suspension of *Staphylococcus aureus* Heatley (Oxford 657). The bacterial suspension, a 10^{-5} dilution from an 18-hr. culture in nutrient broth at 37° C., was prepared according to techniques already described (Portolés, 1960). Experiments were repeated three times and the results are recorded in Fig. 1.

As seen in Fig. 1, the results have been expressed as the minimum inhibitory concentration of 'Kanamycin' per ml. required to avoid the development of *S. aureus*. From these results it is concluded:

(a) That growth of *S. aureus* was inhibited by 0.28 γ ml. of 'Kanamycin' using nutrient as substrate. 0.28 γ ml. was taken as the standard value of 'Kanamycin' activity; (b) that normal rabbit sera had a bacteriostatic activity which was equivalent after proper calculations to 0.19 γ ml. of 'Kanamycin'; (c) that the series of dilutions of 'Kanamycin' in

normal rabbit sera gave an inhibition of *S. aureus* at concentrations ranging from 0.097 γ to 0.12 γ ml.; (d) that the series of dilutions of 'Kanamycin' in immuno-sera obtained from rabbits previously treated with the antibiotic decreased the inhibitory effect of *S. aureus* development. The experiments showed that in this case greater amounts of 'Kanamycin' were required to obtain an effect similar to that of 0.28 γ ml. in nutrient broth. The values increased with the 'time of contact' from 6.35 γ ml. after 4 hr. to 24.63 γ ml. after 24 hr.

Intradermic tests were also made in the treated animals, using 0.15 ml. standard solutions of the antibiotic at 40.0, 20.0, 10.0, 5.0, 1.25, 0.62 and 0.31 γ ml. in distilled water, pyrogen-free, as well as 0.15 ml. of saline solution. All tests were negative.

From these results it seems conclusive that in the sera of rabbits previously treated with 'Kanamycin' there exists a substance which specifically inactivates the antibiotic. The substance apparently acts proportionally to the 'time of contact', for the antibiotic activity of 'Kanamycin' on *S. aureus* is remarkably reduced. The nature of the agent responsible for this blocking action against the antibiotic is not understood. Experiments made up to the present have demonstrated, however, that it cannot be included in the group of precipitins, but more precise results have been obtained by deviation complement tests. The latter results have shown the presence of certain specific anti-'Kanamycin' antibodies at 1/5 sera dilutions against concentrations of 10 mgm. 'Kanamycin' per ml.

The presence of this new factor in the sera of animals treated with an antibiotic suggests the importance of considering in the therapeutics of antibiotics the close interrelationship between the antibiotic and host-organisms as well as the possible influence of the latter relationship in the so-called 'resistance' to antibiotics.

A Rapid Method of preparing Pure Serum Gamma-Globulin

In the course of investigating various methods of isolating skin-sensitizing antibodies from human allergic serum, a procedure has been devised which could be applied to the rapid preparation of other 7S-type gamma-globulins in a high degree of purity. The technique employs diethyl amino ethyl cellulose anion exchanger, prepared according to the method used by Peterson and Sober¹, to adsorb out of the serum all proteins other than 7S-type gamma-globulins. For this purpose, a batch process has proved superior to the more widely used column chromatography, because of its greater speed and ease of manipulation.

A small portion (2.5 ml.) of human serum, previously dialysed for 16 hr. at 4° C. against 1 litre of sodium phosphate buffer (pH 7.5, 0.01 M) containing 0.015 M sodium chloride, is added dropwise with continuous stirring to moist diethyl amino ethyl cellulose (17 gm. wet weight) which has been equilibrated and mixed with 2.5 ml. of similar buffer

Fig. 1. Immunoelectrophoretic patterns of human serum (S) and purified gamma-globulin fractions (I and II) after testing with rabbit anti-human serum (A/S) and anti-human gamma-globulin (A/γ).

pre-cooled to 4° C. After the mixture has stood at 4° C. for 5 hr., a further 5 ml. of buffer is added with stirring and the resultant slurry is centrifuged in a cooled tube at 3,000 r.p.m. for 15 min. The supernatant (fraction I) contains highly pure gamma-globulin in a concentration of the order of 100–200 mgm./100 ml. (comprising a yield of approximately 50 per cent). A slightly less pure preparation (fraction II) is obtained by a repeat rinse of the exchanger with a further 5 ml. of phosphate buffer (0.01 M), still at pH 7.5.

The immunoelectrophoretic patterns shown in Fig. 1, obtained by testing with rabbit anti-human serum and anti-human gamma-globulin, reveal fractions I and II to be composed entirely of gamma-globulin. Small amounts (1–3 per cent) of a beta-globulin contaminant—probably siderophilin—can be detected, however, by testing with a more potent specific antiserum against alpha- and beta-globulins.

Quantitative gel-diffusion precipitin analyses with specific rabbit-antisera against alpha₂-glycoprotein and 19S-type gamma-globulin (kindly carried out by Dr. J. F. Soothill) demonstrated that the gamma-globulin fractions I and II were completely free from these high-molecular weight proteins. This finding was substantiated by *iso*-agglutinin titrations, employing type A and type B cells, which failed to detect any activity in either fraction although the initial serum possessed a 1/32 titre against type A cells and a 1/16 titre against type B cells.

As seen in Fig. 2, analytical ultracentrifugation in a Spinco model E machine also failed to reveal any 19S-type component (in fraction I and II solutions containing approximately 300 mgm. protein/100 ml.).

Fig. 2. Ultracentrifugal patterns of gamma-globulin fraction I concentrated two-fold by ultrafiltration. Protein concentration, approximately 300 mgm./100 ml., solvent, sodium phosphate buffer (pH 6.9, 0.06 M) containing 0.15 M sodium chloride; speed, 60,000 rev./min., temperature, 20° C.; $S_{20,w} = 6.9S$.

It is also interesting to note the absence of 10S-type component, which often appears in gamma-globulin preparations obtained by low-temperature procedures with ethanol and ether; nor could any 4.5S component be detected.

The batch process outlined above can be speeded up by omitting the initial overnight equilibration of serum with buffer, although this results in the sacrifice of a slight degree of purity of the gamma-globulin obtained. This modification offers an additional advantage, however, in that the whole procedure can then be more readily carried out under aseptic conditions. Such an adaptation has proved most useful in the preparation of skin-sensitizing antibody fractions (unpublished work), which have to be assayed by passive transfer into human recipients.

Summarizing briefly, the method described provides a convenient way of obtaining small quantities of purified gamma-globulin quickly and with minimum manipulation by a relatively mild treatment. It seems probable that it could be extended to preparations on a considerably larger scale.

I acknowledge the interest Prof. J. R. Squire has taken in this work. Ultracentrifugal analyses were carried out by Miss P. Ratcliff on a machine generously provided by the Rockefeller Foundation, New York.

Inhibition of Ehrlich Ascites Tumour Growth by Surface-active Agents

A RECENT communication by Townsend, Morgan and Hazlett¹ suggests that admixture of 10-hydroxy-Δ²-decanoic acid with tumour cells will prevent growth of the cells on inoculation into mice. Similar results have been obtained by this group with other dicarboxylic acids². In the course of work on the action of surface-active agents on tumour cell membranes³, we have noted similar inhibition of growth of Ehrlich ascites tumour cells.

Ehrlich ascites tumour was grown in Swiss mice and removed after seven days. The cells were washed in sterile 0.15 M saline and resuspended in the same solution. Surfactant was added to the desired concentration, an aliquot removed for counting⁴, and portions of the remainder used to inoculate mice. The final concentrations of surfactants were those known to foster 100, 99, 90 or 50 per cent staining by nigrosin. Groups of five mice were used for each concentration. The survivals of mice injected with our strain of Ehrlich ascites, untreated, are shown in Table 1.

Table 1. SURVIVAL OF MICE INOCULATED WITH GRADED NUMBERS OF UNTREATED EHRLICH ASCITES CELLS

Log No. cells	No. of mice (tumours/inoculated)	Days to death from tumour*
1	0/7	†
2	0/10	†
3	0/10	†
4	3/5	23–80 (42)
5	5/5	15–21 (18)
6	5/5	15–21 (19)

* Figures in parentheses are averages.

	4	99	0/4		Toxic
	5	90	0/4		Toxic
	5.7	50	0/4		Toxic

* Log total cells = 6. † Killed at 68 days and no tumour found ‡ Figures in parentheses are averages.

As is apparent from Table 2, admixture of sodium lauryl sulphate caused an inhibition of tumour formation which is roughly comparable to the increased ability of the cells to take up dye, although there is more than a ten-fold difference in the minimum number of unstained ('viable') cells necessary to produce ascites. In contrast, when the non-ionic surfactant 'Igepal DM-710' (a polyoxyethylated nonyl-phenol of molecular weight approximately 1300) was employed, no tumours were observed at the end of 68 days, even when the final concentration of unstained cells was 500,000. Cells treated with lauryl pyridinium chloride proved toxic to the animals. 10-Hydroxy-decenoic acid, in citrate buffer of pH 5.5, permits only 37 per cent of the cells to pick up dye (acid concentration 3 mgm. per ml.).

At pH 4.3 in phosphate buffer, initially 10 per cent of the cells stained. The figure was not changed immediately by addition of 10-hydroxydecenoic acid, but after 20 min. 70 per cent of the cells exhibited staining. Morphologically, there was no lysis. The cells were wrinkled yet intact as compared to the loss of cytoplasm after treatment with sodium lauryl sulphate or 'Igepal DM-710'. Details of these changes will be reported elsewhere.

Attempts were made to inhibit tumour-growth *in vivo* by intraperitoneal administration of sodium lauryl sulphate and 'DM-710'. Mice were injected with 10^6 cells. One week later all the ascitic fluid obtainable was removed by syringe aspiration. Each mouse was injected with 1 ml. 0.014 M surfactant. Samples of ascitic fluid were withdrawn 24 hr. later, and nigrosin uptake determined. The controls and animals treated with sodium lauryl sulphate showed 3 per cent dye uptake; the 'DM-710' treated, 12 per cent. The control animals died in an additional eight days (average), those treated with sodium lauryl sulphate in four, and those treated with 'DM-710' in two. All had typical tumour at autopsy.

In view of the results obtained to date, it appears that while inhibition of tumour growth can be obtained with a number of agents, the mode of action of these substances differs. One might speculate that some agents act by altering the cell surfaces, while others may complex vital proteins, inhibit enzymes, or interfere with fatty acid metabolism. It is obvious that alterations in the ability of cells to take up dye are not always correlated with death of the cells⁵.

This work was supported in part by grants from the U.S. Public Health Service (CY-3475(C2)), Damon Runyon Memorial Fund (DRG-426A) and the

Leukemia Society, Inc. Surfactants were gifts from E. I. DuPont de Nemours and Co., Antara Chemical and Hooker Chemical Co. The 10-hydroxydecenoic acid was a gift from Prof. Butenandt of Munich.

ANATOMY

Intracellular Canals in Human Sweat Glands

HIBBS¹ has demonstrated the existence of intercellular canaliculi in human eccrine sweat glands by electron microscopy and found them to be situated in the coiled secretory portion of the glands only. He was unable to recognize intracellular canaliculi, however. These intercellular canaliculi can be seen from his illustrations to be lined by a plasma membrane which shows many micro-villi projecting into the lumen. This lumen contains a moderately homogeneous matrix of low density and several indistinct granular profiles, possibly in the nature of a secretion.

The present communication describes the finding of structures resembling intracellular canaliculi in human eccrine sweat glands. As in Hibbs's cases these were found in the coiled secretory portion of the gland. But in contrast to those in his cases, which were from adult Negro volar skin, they were found in the abdominal skin of a 5-year-old white girl; the biopsy being taken immediately on making the incision for a nephrectomy.

The appearances of these structures are exemplified by that shown in Fig. 1. The lumen (X) can be seen to be surrounded by a plasma membrane folded into many micro-villi. It also contains a low-density matrix and several more dense but ill-

Fig. 1. Electron micrograph of a secretory cell of a human eccrine sweat gland (abdominal skin). The structure (X) shows the typical appearances of an intercellular canal, but lies wholly within the cytoplasm. The adjacent structure (G) is the Golgi complex. (Palade's osmium tetroxide fixative. $\times 10,800$)

defined granular profiles. These appearances are virtually identical with those reported by Hibbs. It can also be seen from the illustration that the structure lies wholly within one cell. That is to say, cell boundaries are not seen anywhere near it, nor more

Fig. 2. A different part of the same sweat coil depicted in Fig. 1. IC, intercellular canal; S, intracellular sinus or canal; M, double membrane with desmosomes. (Palade's osmium tetroxide fixative. $\times 13,400$)

importantly, are any contiguous with its limiting membrane. It is of interest, and may also be of significance, that it is lying close to the vesicular profiles of the Golgi complex (G).

In Fig. 2 can be seen an intercellular canaliculus (IC) together with a similar structure (S) apparently lying entirely within the cytoplasm of the cell. That this is not a true intracellular canaliculus is suggested by its close proximity to the double cell membrane (M), which can be seen to possess desmosomes.

By definition a canaliculus must commence and end somewhere. It may be that the structure described here joins two intercellular canaliculi or joins an intercellular canal to the lumen of the coil. On the other hand, it might take the form of a blind sinus, communicating at one end with the lumen or with an intercellular canal, the blind end lying wholly within the cytoplasm.

It has not yet been possible to decide whether these structures are intercellular canaliculi or merely blind sinuses, or whether they are permanent or temporary.

I wish to thank Dr. I. Friedmann and the Institute of Otolaryngology, University of London, for putting the facilities of their electron microscope at my disposal.

Lymph Node Reactivity to Homografts of Cancellous Bone

N. A. MITCHISON¹ first showed that the power to transfer immunity caused by lymphosarcoma 6C3HED to non-susceptible mice is confined to the lymph nodes draining the site of implantation. Billingham *et al.*² also found that in mice the tissues of the host which have the power to transfer immunity to skin homografts are the regional nodes and to a lesser degree the spleen. Gallone³ and his colleagues had previously shown that an increase in pyronin-staining cells occurred in the lymph nodes draining skin homografts. This work was confirmed and extended by Scothorne and McGregor⁴, who showed that in rabbits a considerable increase in weight occurred in lymph nodes draining homografts, but not autografts, of skin. Further, they showed that after homografting, great accumulations of 'large lymphoid cells' appeared in the cortex and to a lesser extent in the medullary cords of the draining lymph nodes. The cellular response waned rapidly with the onset of graft destruction, and within two days the nodes were largely depleted of pyroninophilic elements. Radici and Piredda⁵, also using rabbits, have described how, five days after a skin homograft, the reticular cells of the medullary cords of the first regional node are in large part replaced by pyroninophilic cells. Craigmyle⁶, however, using cartilage, was able to show that the weight changes and cytological alterations in the regional lymph nodes occurred, but only in response to second-set homografts and first-set heterografts of cartilage. He concluded that cartilage in the rabbit is only mildly antigenic.

The reaction of the first regional lymph node to a constant weight (95–100 mgm.) of fresh cancellous bone removed from the ilium of five albino rabbits

Fig. 1. Graphs of the mean weight increments, with standard errors, of the first regional lymph nodes after homografts (—) and autografts (---) of cancellous bone

and inserted into the subcutaneous tissue of the ear in fifty-one Flemish Giant rabbits has been investigated. Control animals were provided by nineteen Flemish Giants which received autografts of cancellous bone into the subcutaneous tissue of the ear. The animals were killed at intervals of 2–21 days after operation. The first regional lymph nodes on both sides were removed, weighed and fixed in Carnoy's fluid, embedded in paraffin, cut at 6μ and stained with methyl green-pyronin.

The mean weight increments and standard errors of the first regional lymph nodes for the homografted and the autografted animals at various time-intervals after grafting are shown in Fig. 1. An overall test of the difference between the homograft nodes on one hand, and the autograft nodes on the other, has been made by combining the values of P for each time-interval, using the method described by Fisher⁷. This test of significance gave $P < 0.005$, showing that overall, the difference in mean weight increments of the homografted and the autografted nodes was highly significant.

Histological examination of the lymph nodes reacting to bone homografts has revealed great numbers of pyroninophilic large and medium lymphoid cells in the diffuse cortical tissue and in the medullary cords. Further analysis of the nodes has

Fig. 2. Camera lucida tracing of a section from a first regional lymph node removed four days after homografting. The distribution of large and medium lymphoid cells in the cortex is shown by stippling. The method of selective sampling of the reactive cortex is indicated by the isobaths. (GC = germinal centre; PCSL = peripheral collection of small lymphocytes)

shown a sectoral distribution (Fig. 2) of these pyroninophilic cells which is probably due to the entry of the 'homograft factor' to that particular part of the cortex. To put this probability to the test, 0.1 ml. indian ink was injected subcutaneously into the ear on the ventral aspect in two rabbits, 1 centimetre from the external auditory meatus. The first regional lymph nodes were removed $\frac{1}{2}$ hr. later, fixed, embedded and sectioned. Indian ink was found to be distributed to only one side of the nodes. Hence the conclusion that the sectoral distribution of the large and medium lymphoid cell response is due to the localized entry of antigenic material from the bone homograft to a particular part of the lymph node appears justified.

Fig. 3. Graphs of the means, with standard errors, of the counts of large and medium lymphoid cells in the reactive diffuse lymphoid tissue of the cortex from normal (---) and homografted (—) lymph nodes

A quantitative analysis of the large and medium lymphoid cell response has been attempted in the reactive sectors of the diffuse lymphoid tissue of the cortex in twenty-four nodes removed 2–14 days after homografting. Counts have been made in three different sections from each node in fields of $57\mu^2$, using $\times 10$ eyepieces and a $\times 100$ oil immersion objective. The counts were made two graticule divisions apart on lines (or isobaths) four, eight and less frequently twelve, graticule divisions from the surfaces of the nodes (Fig. 2). The mean number of large and medium lymphoid cells per unit area of reactive cortex for three nodes at each time-interval has been found to rise rapidly and reach a maximum between the fourth and sixth day after homografting (Fig. 3). A more gradual decline then ensues, the count returning to a normal level by the fourteenth day after insertion of the graft.

A more detailed account of these results will shortly be published together with the results of an immunological examination of the sera of these animals.

BIOPHYSICS

Automatic Equipment for the Collection and Processing of Data from Geiger-Müller Counters

DURING a radioisotopic investigation of ion accumulation processes in marine algae it became apparent that a considerable amount of data required to be collected over extended periods of time. Automatic equipment was therefore devised both for the collection and preliminary processing of the information.

Geiger counters (type GM4) with their aluminium end-windows protected by epoxy-resin paint are fixed directly above algal sections contained in shallow cavities through which seawater incorporating the radioisotope being studied is rapidly circulated. (A description of the section holder and circulator assemblies is being submitted for publication elsewhere.) The voltage pulses from probe units to which sets of the Geiger counters are sequentially connected are recorded on a standard tape recorder at a tape speed of $1\frac{1}{2}$ in. per sec., the frequency response at this speed being adequate to record without loss of counts from a probe unit with 500 μ sec. paralysis time. The number of Geiger counters in a sequence, the periods for which counts are taken and the interval between successive count periods can be pre-set on a programming unit. As the tape recorder motors are switched on only for a duration determined by the programming unit (in practice 1 min. longer than the count period) a single spool of tape can accommodate large numbers of count periods, for example, a 2,400-ft. spool can permit the recording of more than 120 sets of counts of 1-min. duration on each of its two tracks. Originally the reproduction of this data in usable form was a time-consuming task despite the utilization of a playback speed eight times that of recording, but recently a simple data-processing machine has been completed.

The pulses replayed from the two tracks of the magnetic tape are fed into two scalars each provided with dividing circuits, the division ratios corresponding to the times for which the original counts were recorded. The scalars thus indicate directly the counts per minute on their main registers. Each scalar has a subsidiary register on which the dead-time correction factor is automatically computed. On receipt of a signal which is recorded on the tape at the end of each count period and which is isolated by a two-stage frequency-selective network, a read-out and print-out sequence is initiated. In addition to printing out the counts per minute and the dead-time correction factors, a solenoid-operated calculating machine also prints the starting count per minute for each Geiger counter selected in the original sequence together with counter identification numbers. The calculating machine can perform simple operations on the data being printed out such as producing automatically a difference between the newly determined count per minute and starting count per minute. In the majority of cases, this difference is sufficiently satisfactory for direct graphical representation to indicate the course of an experiment without the application of the dead-time correction factor though, if required, the data for dead-time correction are immediately available without reference to tables. On completion of the

print-out sequence the scaling and computing circuits are automatically reset.

This simple computing equipment, while designed specifically to deal with tape-recorded data, can be used with advantage for routine Geiger counting wherever large numbers of samples have to be dealt with and is thus felt to be of wider interest.

I am grateful to the Extra-mural Research Section of the United Kingdom Atomic Energy Authority for financial assistance in the construction of the equipment and for permission to publish this description.

Identification of Ultracentrifugal Components in Human Plasminogen Preparations

SAMPLES of human plasminogen, prepared according to the method of Kline¹, have been subjected to ultracentrifugal analysis². The patterns observed contained two sedimenting peaks. The slower peak constituted approximately 70 per cent of the total area and had a sedimentation constant, $s_{20,w}$, of 4.28 *S*, extrapolated to infinite dilution. The faster peak, which was much broader and resolved poorly from the main component, had a sedimentation constant of about 7–10 *S*. It was merely assumed that plasminogen was to be identified with the 4.3 *S*-component, and on this basis, along with other data, molecular size and shape were estimated. We now report direct evidence to substantiate this assumption.

The proteolytic activity was measured by casein assay, essentially according to Remmert and Cohen³, except that the casein concentration was 2 instead of 4 per cent. The concentration of protein in the sample being assayed was measured by light absorption at 2800 Å., using 14.0 as extinction coefficient². The activity is therefore expressed as casein units/mgm. protein.

Sedimentation studies were made in a Spinco model *E* ultracentrifuge, using an analytical cell with a 2° sector to minimize the volume required, and a standard fixed-partition cell for separation of components. These runs were made on samples that had been dialysed against acid-saline (0.15 *M* sodium chloride + 0.01 *N* hydrochloric acid, pH 2).

In an early separation experiment, a solution at 1.4 per cent concentration was run in the separation cell until the fast component had apparently gone past the partition. After terminating the run, samples were obtained from the top compartment ('Top') and the bottom compartment ('Bottom'), 0.2 ml. each, and diluted with 1.5 ml. of acid-saline. These dilutions were measured for protein content and assayed on casein. A sample of the initial solution was allowed to stand at room temperature during the run ('Warm control') and another solution was kept refrigerated ('Cold control'). These were similarly diluted and assayed. The results are shown in Table 1. This experiment is adequate proof that the proenzyme is to be associated with the slow component. If it were in the fast peak, the activity in 'Top' should be considerably reduced, although not to zero, since the boundary is quite broad; instead

Table 1. PROTEOLYTIC ACTIVITY OF HUMAN PLASMINOGEN AND ULTRACENTRIFUGAL FRACTIONS

Sample	Specific activity (units/mgm.)
Cold control	3.9
Warm control	3.5
Top	6.6
Bottom	3.9

Table 2. PROTEOLYTIC ACTIVITY AND ULTRACENTRIFUGAL ANALYSIS OF HUMAN PLASMINOGEN AND ULTRACENTRIFUGAL FRACTIONS

Sample	Specific activity (units/mgm.)	Relative amount of 4.3 S-component (per cent)
Warm control	4.4	70.2
Top	7.8	93.6
Bottom	7.1	88.8

it is increased, as would be expected from removal of inert proteins.

The experiment was repeated, however, with results that were equivocal, as was true in several additional trials. The problem seemed to be due to the difficulty of judging the proper degree of dilution to avoid a protein-level that was too low (poor sensitivity) or too high (non-linearity) for the casein assay. I decided to perform a series of separation runs, in order to pool the respective products. There would thus be enough material to be checked by analytical ultracentrifugation. A group of six separation runs were pooled and yielded 1.96 ml. of 'Top' and 1.07 ml. of 'Bottom'. The sedimentation pattern of the initial sample is shown in Fig. 1. On re-examining the fractions, at similar concentrations, sedimentation patterns as in Fig. 2 were observed. The measured proportions for these samples are shown in Table 2, along with the assay data. It can be seen that 'Top' does contain considerable enrichment of slow peak, and even 'Bottom' shows a similar enrich-

Fig. 1. Ultracentrifugal pattern of human plasminogen (by Kline method). Concentration of protein, 0.80 per cent; bar angle, 40°; photograph at 16 min.; rotor speed, 59,780 r.p.m.

Fig. 2. Ultracentrifugal pattern of human plasminogen fractionated in separation cell. 'Top' fraction on left. Concentration of protein, 0.88 per cent; bar angle, 40°; photograph at 20 min. 'Bottom' fraction on right. Concentration of protein, 0.80 per cent; bar angle, 40°; photograph at 20 min.; rotor speed, 59,780 r.p.m.

ment. Both fractions show an increased specific activity, fully in accord with the first experiment. In fact, if one plots casein activity for these three samples against percentage of 4.3 S-component, a quite acceptable straight line is observed. One can conclude, therefore, that the fast peak represents an inert contaminant. In addition, it is seen that a purification of about 1.8-fold can be achieved by ultracentrifugation. Studies of fractionation with ammonium sulphate, leading to similar conclusions, as well as to electrophoretic identifications, will be published elsewhere.

Technical assistance was provided by Mr. Ivan Kawai. This investigation was supported in part by a research grant, H-1792, from the National Heart Institute, Public Health Service, and also by a Senior Research Fellowship (SF-118) from the Public Health Service.

BIOLOGY

Surface of a Parasite and the Hæmocytic Reaction of its Host

EXPERIMENTS recorded in a recent paper¹ have shown that the hæmocytic reaction of insects to parasites and other foreign bodies in their hæmocoele is stimulated by properties of the surfaces of those objects. In an article² the publication of which has been delayed, I have brought together observations which suggest that the hæmocytes of an insect react to any surface which lacks specific properties of the surfaces which they themselves lay down, or contribute to, about the organs and tissues of the insect of which they form part.

If that hypothesis is correct, a foreign body that has caused a reaction and has been encapsulated by blood cells might be expected thereby to have acquired a surface that would render it immune to further reaction from the same or a similar host. That this is so was demonstrated¹ by implanting an object in the haemocoel of an insect and, after it had been encapsulated, transferring the object and the unbroken capsule about it to another host. Objects thus transplanted to individuals of the same species evoked no visible response; those transplanted to hosts of a different kind stimulated another haemocytic reaction which led to the encapsulated object being enveloped in a second capsule formed by the blood cells of the second host.

The hypothesis has recently been tested in the reverse way, by altering a surface that confers immunity to the reaction and finding that the reaction then takes place. It is well known that living larvae of the parasitoid *Nemeritis canescens* stimulate no reaction on the part of the haemocytes of their normal host, *Ephestia sericarium*, so long as their surface is unbroken; although, if their surface is minutely perforated, as by the mandibles of a competing parasite, haemocytes of the host congregate locally about the wound. These larvae therefore provide suitable material for examination of an immune surface. When first-instar larvae of *Nemeritis* were put individually into a variety of fluids, removed and washed for some hours in insect saline, and then implanted in *Ephestia*, two groups of significant results were observed. After immersion in some fluids, the implanted parasites evoked no reaction, but fed and developed normally in their new hosts. After immersion in other fluids, however, the implanted living parasites provoked a haemocytic reaction in their normal hosts and were found completely covered in a thick layer of haemocytes. Within that layer they were still alive and moving vigorously as though attempting to divest themselves of the haemocytic covering.

Various fluids have been used in experiments of this pattern, the period of immersion in them being adjusted to allow survival of the parasite larvae. So far as the experiments have yet gone, all the fluids found to have the second result, that is, to expose the parasite to encapsulation in its normal host, have been solvents of fats. Octane has been found especially efficient. It appears from these observations that the removal of a lipid constituent of the surface of *Nemeritis* larvae also removes the specific properties that provide its immunity to the haemocytic reaction of *Ephestia*.

A few parallel experiments have been carried out using testes of *Ephestia* for implantation. As is common knowledge, if these organs are removed from an insect and implanted in another individual of the same species, they evoke no general haemocytic reaction; but if implanted in quite different hosts they are encapsulated. When entire *Ephestia* testes were immersed in fluids found to be effective in the experiments with *Nemeritis* larvae, washed in saline, and implanted in other *Ephestia*, they were encapsulated. These experiments give direct support to the hypothesis put forward, but are not as critical as those involving parasite larvae because it is not easily possible to observe whether the encapsulated testes are sound and healthy. It is the fact that larvae of *Nemeritis* can be retrieved from *Ephestia* alive and vigorous although encapsulated that makes

them so useful as experimental objects for examining the surface properties that confer immunity to insect parasites in their normal hosts.

A full account of this and related work will be published elsewhere.

Gestation Time for Delayed Birth in the Quokka

SHARMAN¹ has established that normal gestation time for the Rottneest Island quokka (*Setonix brachyurus*) is twenty-seven days. He has further shown that, in delayed birth in this species, the unilaminar blastocyst stage at which development is arrested occurs about three days after copulation. It is of interest to assess the time necessary from resumption of development of the blastocyst to parturition after the impetus to growth, that is, removal of the initial joey, is applied.

A sample of 40 females with pouch young were caught on Rottneest Island. The joeys were removed and the females taken to the mainland where they were retained in isolation from males. The pouches were examined for the presence of a second joey on the days indicated in Table 1. From Table 1 it is seen that three joeys were born twenty-five days after the removal of the initial joeys, but the majority of births occurred on the twenty-sixth day. Taking twenty-six days as the further gestation time of the blastocyst, which had taken three days to achieve the stage at which development was arrested, it appears that the total gestation time for the 'delayed' joey is twenty-nine days. Since normal gestation time is twenty-seven days, it seems that two days are necessary for resumption of development of the quiescent blastocyst.

Table 1. INTERVAL IN DAYS BETWEEN THE REMOVAL OF THE INITIAL JOEY AND THE BIRTH OF THE 'DELAYED' JOEY

Day	23	24	25	26	27
No. of pouches examined	35	37	40	36	22
No. of joeys found	0	0	3	14	0

During the course of this experiment and other work data were collected on the sex of the initial joey and that of the subsequent 'delayed' joey. Table 2 shows no significant association between the sex of the initial and 'delayed' joeys. This is presented in confirmation of Sharman's finding that the 'delayed' joey is the result of a separate ovulation, and no process analogous to twinning occurs.

Table 2. RELATIONSHIP BETWEEN THE SEX OF THE INITIAL JOEY AND THAT OF THE 'DELAYED' JOEY

		Initial joeys		
		Males	Females	Total
'Delayed' joeys	Males	3	7	10
	Females	5	8	13
		8	15	23

Electron Microscopy of Thysanuran Spermogenesis

In a recent discussion^{1,2} on the position of the acrosome and centriole in the thysanuran spermatozoon, the necessity for electron microscopy was stressed. In Fig. 1, the Golgi body (acroblast; *G*) is lying to one side of the very large acrosome (*A*). Below is the nucleus (*N*). The flagellum has grown out inside the cell and is cut across in three places (*F*₁–*F*₃). On the right is a constantly occurring body (*CA*), which at present is considered to be a centriole adjunct, as in other micrographs it is found near the centriole. Cross-sections of the ripe or nearly ripe sperms are shown in Fig. 2. The anteriorly situated acrosome has become a scoop-shaped body (*A*), which passes back to form a tube (*B*), which joins the nucleus (*C*), which passes back to join the flagellum (*F*). No adnuclear thread or flagellum is found on the tubular nucleus, but there is an intranuclear body (*X*), which projects up into the funnel

of the acrosome. This is probably what is seen with the light microscope in the form of an intra-nuclear flagellum. This body, however, does not possess the flagellar ultrastructures.

A fuller account of this spermiogenesis, and that of *Lepisma*, will be published elsewhere. I thank M. Jean André of the Electron Microscopy Department of the Institut de Recherches sur le Cancer, Villejuif (Seine), for taking the micrographs.

Influence of Amino Triazole on the Chloroplast Pigments of Wheat Seedlings

3-AMINO-1,2,4-TRIAZOLE is a chemical which has several effects on higher plants. It is a growth inhibitor, and has been used on cotton plants as a defoliant¹. Hall *et al.* demonstrated that tissues formed subsequent to application of this chemical have a decreased chlorophyll content, while the chlorophyll-level of already mature tissues is unaffected. It was not entirely clear to these investigators whether the observed effect of amino triazole on chlorophyll content is due to chlorophyll destruction or to interference with chlorophyll synthesis. The structural similarity of the triazole ring to the pyrrole rings of chlorophyll prompted the suggestion that amino triazole brings about a block in chlorophyll synthesis prior to the protochlorophyll stage by a competitive inhibitory mechanism¹. This concept was somewhat strengthened when it was found that levels of catalase, which has a similar structure, were also decreased in both plants and animals by treatment with amino triazole^{2,3}.

Experiments with *Elodea canadensis* further served to localize the effect of amino triazole as influencing chlorophyll synthesis rather than chlorophyll destruction, but microscopic observations clearly indicated interference with plastid development⁴. This suggested the possibility that the influence of amino triazole on chlorophyll content might be secondary to an effect on the development of the plastid as a whole. According to Pyfrom *et al.*⁵, "a small amount of amino triazole interferes with the plastids during leaf formation or differentiation, and chlorophyll as well as other plastid pigments are always low in these leaves".

In an effort to secure further insight into this situation, wheat grains were germinated and seedlings were grown in Petri dishes containing filter paper, moistened with water or with various concentrations of amino triazole. The conditions of growth were identical with those described by Haber and Luippold⁵ with 400–500 ft.-candles of white light during a 16-hr. day. Analyses for chlorophyll *a*, chlorophyll *b*, and total carotenoids were performed according to the technique of Röbbelen⁶. After preliminary trials with various concentrations of amino triazole, a concentration of 10⁻⁴ M was selected, which permitted about 70 per cent of normal growth during a 12-day period, yet reduced the chlorophyll content to a value approximating 5 per cent of normal.

Wheat seedlings were germinated in darkness, in either 10⁻⁴ M amino triazole or in water. After 6 days, the etiolated seedlings were placed under a light source of the type described by Withrow and

Figs. 1 and 2

Fig. 1. Greening of 6-day old wheat seedlings, as influenced by 10^{-4} M amino triazole. —, Control; ---, amino triazole

Elstad⁷, which provided a light intensity of 1,000 ft.-candles. Determinations of total chlorophylls (*a* plus *b*) were made at intervals during the subsequent 36 hr. The results (Fig. 1) indicate that normal greening was drastically inhibited by this concentration of amino triazole.

In another type of experiment, wheat seedlings were grown in water under the usual 16-hr. photoperiod. After 6 days, the water in some of the dishes was replaced by 10^{-4} M amino triazole, and all the plants were placed in darkness. Chlorophyll estimations were made at 2-day intervals over a period of 10 days. The findings (Fig. 2) indicate no difference in the rate of chlorophyll disappearance in darkness as a result of treatment with amino triazole.

Wheat seedlings were grown in water under a 16-hr. photoperiod for 6 days, and were then transferred to 10^{-4} M amino triazole. When such plants were continued under the 16-hr. photoperiod, their subsequent appearance was very striking. The basal portion of the leaves was a normal green in colour. Distal to the green area was a colourless zone about 1 cm. in length, while the portions of the leaves produced after treatment with amino triazole were a reddish-purple in colour, owing to the abundant production of an anthocyanin pigment, which was not detected in untreated plants. Further, this effect was not noted in plants treated similarly, but placed in darkness following treatment with amino triazole.

Wheat grains were germinated in the presence of amino triazole in concentrations ranging from 1×10^{-5} M to 2×10^{-4} M. After 12 days of growth

Fig. 2. Disappearance of chlorophyll from 6-day old wheat seedlings, in darkness, as influenced by 10^{-4} M amino triazole. —, Control; ---, amino triazole

under the usual 16-hr. photoperiod, analyses for total carotenoids and chlorophyll were made. The results (Table 1) indicate that the reduction in chlorophyll content resulting from treatment with amino triazole is accompanied by reductions of similar magnitude in the carotenoid pigments.

Table 1. PIGMENT CONTENT OF WHEAT SEEDLINGS GROWN FOR 12 DAYS IN VARIOUS CONCENTRATIONS OF AMINO TRIAZOLE

Concentration of amino triazole	Height (mm.)	Chlorophyll/plant (%)	Carotenoids/plant (%)
0 (Control)	105.2	56.6	12.7
1×10^{-5} M	98.9	46.8	11.0
2×10^{-5} M	93.8	26.8	6.7
4×10^{-5} M	77.5	7.3	1.3
1×10^{-4} M	72.1	2.0	0.5
2×10^{-4} M	38.3	1.7	0.3

In summary, the greening experiment indicates that the net rate of chlorophyll synthesis (excess of synthesis over destruction) is drastically reduced by amino triazole. There would appear to be no direct action of amino triazole on the rate of chlorophyll destruction, at least in darkness. Considered together, these findings would appear to add further evidence to that of earlier investigators^{1,4} localizing the effect of amino triazole on the synthesis of chlorophyll. But since amino triazole has a similar influence on the levels of both carotenoids and chlorophyll: (1) the hypothesis of Hall *et al.*¹ which considers amino triazole as a competitive inhibitor of chlorophyll synthesis is incorrect, and (2) it would seem reasonable to suppose, confirmatory of earlier findings^{3,4}, that the effects of amino triazole on plastid pigments are secondary to an effect upon the plastid itself.

Complex Particles in Hevea Latex

LATEX freshly tapped from *Hevea brasiliensis* is known to contain particles other than rubber. By high-speed centrifugation, Cook and Sekhar¹ parted such latex into a top fraction and a bottom fraction with serum between. Both fractions are visibly heterogeneous, and Moir² has recently distinguished no less than eleven zones in centrifuged latex. Only three types of particle have been described in the literature so far. These are the rubber particles, often pear shaped, found in the top fraction, the Frey Wyssling particles³, which are yellow bodies found mostly in the lower part of the top fraction, and the 'lutoid' particles of Homans and van Gils⁴. The term 'lutoid' was originally applied to large irregularly shaped islands of a yellowish colour consisting of mainly non-rubber material and seen in whole fresh latex. Ruinen⁵ detected a particulate structure in these islands and uses the term to describe individual globules seen therein. Schoon and Phoa⁶ mention that 'inside the lutoid vacuoles, in a few cases very

small particles are to be observed in Brownian motion". Up to date, no photographs of this phenomenon have been published.

I am at present carrying out an examination by microscopy of latex fractions separated after high-speed centrifugation. The technique of collection and centrifugation described by Moir² is used, the latex being tapped directly into a glass container surrounded by melting ice and the temperature kept below 5° C. throughout the preparative procedures. In such material from both mature and young trees, I have observed a distinct type of particle occurring abundantly in the bottom fraction from high-speed centrifugation, and forming the bulk of Moir's zone 8².

In the initial and intact state they are spheres of 2–10 μ diameter. They have an external membrane which in a medium of suitable refractive index can be made transparent. The interior is fluid and contains very many smaller particles, in size from 1 μ down to the lower limit of visibility. These small captive particles are in vigorous motion and can be seen to strike the containing wall frequently and to be deflected back into the interior (Fig. 1).

Fig. 1. A group of complex particles, slightly aggregated after centrifugation at 54,000g, resuspended in viscous ammonium polymethacrylate-water medium of refractive index 1.371. Photographed with Leitz 'Multiblit' electronic flash illuminant at 300 joules to arrest internal motion, using Reichert anoptical phase 100 $\times$ oil objective matched to Reichert variable phase condenser 'Polyphos'.

After tapping, the particle membranes soon show signs of disintegration. Before this goes very far, the independent motion of the captive particles usually stops; they migrate to the walls and stick there. The membranes themselves readily adhere to each other to form loose agglomerates which later lose their definite internal structure and appear as confused irregular shaped masses.

These particles have also been observed in preparations of whole latex using an electron microscope (Fig. 2). This work was done in Germany using the following procedure to get a supply of fresh *Hevea* latex. A section of the trunk of a 3½-year-old clonal bud-grafted rubber tree (RRIM 603), approximately 1 m. long and 10 cm. diameter, was cut in Malaya and the ends were waxed. The specimen was sent by air to Germany sealed in polythene to reduce losses of moisture. Latex could be tapped for 10 days after the original cutting. Carl Zeiss (Oberkochen) provided laboratory facilities and the use of their Zeiss/AEG EM8 electron microscope.

Fig. 2. Electron micrograph of a carbon pseudo replica from a smear preparation of latex taken with the Zeiss/AEG electron microscope at low magnification. An attempt was made to remove rubber particles by washing with benzene.

The nature and function of these complex particles are not yet understood and are the subject of further investigation. Their appearance tallies with the description of Schoon and Phoa⁶ for a type of lutoid; but in this case they are much more abundant than was supposed. Suggestions that rubber synthesis takes place within a plastid have long been current. For example, Milanez⁷ described 'galactoplastids' in sectioned stained plant material from *Hevea brasiliensis*. Whether or not the particles now seen are related to the galactoplastids of Milanez, the existence of large numbers of such complex particles in latex has an important bearing on the controversy as to whether latex is whole cytoplasm or vacuolar sap and favours the first proposition.

I am indebted to Dr. Grehn and his co-workers at Leitz G.m.b.H., Wetzlar, for their invaluable advice on optical methods, also to Dr. Mahl of Carl Zeiss, Oberkochen/Württ., for his help with the electron micrograph, and to W. G. Wren and P. De Jonge for the preparation of the tree sample for dispatch to me in Germany.

A Comparison of Three Methods for the Assessment of Fungal Colonization of Seedling Roots of Leek and Broad Bean

In recent years several methods have been devised for the isolation of fungi from root tissues. The Harley and Waid serial washing technique¹ has already provided valuable data on fungi closely associated with plant roots^{2,3}, but it has been suggested that the plating of washed root segments in this method does not always allow the isolation of slow-growing forms (such as Basidiomycetes), these being unable to compete with the faster growing fungi. Methods such as root maceration⁴ and root fragmentation⁵ have been claimed to provide a more

complete picture of root mycofloras. The experiments described here compare these three methods for the isolation of fungi from healthy seedling roots of leek (*Allium porrum* L.) and broad bean (*Vicia faba* L.).

Plants of both species were grown under greenhouse conditions in a grassland soil (pH 5.8) and were sampled 30–35 days after sowing. Before any isolations of fungi were attempted the roots were thoroughly washed, first in tap water to remove all visible soil particles and then in sterile water. Preliminary tests had shown that ten 2-min. washings with sterile water allowed efficient washing of the roots.

From this washed root material, isolation of fungi was attempted by the three aforementioned methods (plating of root segments, root maceration and root fragmentation). In all cases isolation of fungi was effected from similar lengths (20 cm.) of healthy root material. The three methods were applied in a manner which in all essential details was the same as that described by their respective authors^{1,4,5}. For all methods Czapek-Dox + yeast extract agar (pH 5.0) was used as the isolation medium and all isolation plates were first incubated at 25° C. for three days and thereafter kept at room temperature, during which time isolation and identification of fungi were effected, and counts made of the number of fungal colonies arising from unit amounts of root material.

Table 1. NUMBER OF FUNGAL ISOLATES, PER UNIT LENGTH OF ROOT, OBTAINED BY THE USE OF DIFFERENT ISOLATION METHODS

Leek			Broad bean	
Root segment plating	Root maceration	Root fragmentation	Root segment plating	Root maceration
34	9	5	70	85
39	12	12	—	117

Results given in Table 1 indicate that, with leek, both root maceration and root fragmentation give fewer isolates from root material than does the direct plating of root segments. However, with broad bean this effect is not seen; in fact, root maceration provides more isolates than does the direct plating of root segments.

The results with leek (*Allium porrum* L.) are similar to those obtained by Timonin and Thexton⁶ with roots of onion (*A. cepa* L.) and garlic (*A. sativum* L.). These authors attempted isolation and enumeration of root surface micro-organisms by plating dilutions of a suspension of root material obtained by shaking roots in sterile water containing glass beads (maceration of the root surface layers occurred). Their results showed that the number of fungi thus obtained was much less than those from dilution plates prepared from the rhizosphere soil of the same two plants.

It is possible that, with leek, chemical substances (possibly diallyl sulphides) possessing fungicidal or fungistatic properties are released during maceration or fragmentation; while the direct plating of root segments, which only causes a small amount of damage to the roots, causes little or no release of these substances. The results with broad bean show no evidence of any such inhibitory effects resulting from root maceration, although an unidentified substance fungicidal to *Aspergillus niger* has been reported⁷ to be present in the stem and root of broad bean.

These results provide support for the suggestion⁸ that maceration or fragmentation techniques, while probably useful for the isolation of fungi from the roots of many species, should be used with caution in view of the possible release of toxic substances during the disruption of the root tissues.

ENTOMOLOGY

Number of Nymphal Instars of the Sugar-cane Froghopper

THERE was some disagreement among earlier authors as to the number of nymphal instars of the sugar-cane froghopper, *Aeneolamia varia saccharina* Distant (Homoptera, Cercopidae). Urich¹ and Williams² considered that there were four instars. Gough³ and Kershaw⁴ both stated that there are five instars; but from their descriptions it would appear that they each recognized a different series.

There are in fact five nymphal instars. This statement is based on the following evidence: (1) measurements of the head-widths of nymphs of all stages collected during one season in the field fall into five distinct groups; (2) the antennae of nymphs in the five different head-width categories differ in size and structure; (3) more than 50 newly hatched nymphs were examined and were found to correspond to the first stage as determined by criteria (1) and (2); (4) two moults have been observed between the true first and second stages.

Table 1. SUMMARY OF CHARACTERS DISTINGUISHING THE FIVE NYMPHAL INSTARS OF *A. varia saccharina*

Instar	Total length (mm.)	Head-width (mm.)	Length of antenna (mm.)	No. of antennal segments
I	1.0–1.5	0.28–0.30	0.14	6
II	1.5–2.0	0.45–0.55	0.22–0.25	6
III	2.5–3.5	0.70–0.80	0.38–0.42	6
IV	4.0–5.5	1.15–1.25	0.60–0.75	6 or 7
V	6.0–8.0	1.65–1.75	1.25–1.40	6, 7 or 8

The characters which distinguish the five instars are summarized in Table 1.

Total length refers to the distance from the tip of the labrum to the tip of the abdomen. It varies with the state of development of the instar and is given here only as a general indication of size. Head-width is the distance between the outer lateral margins of the compound eyes. There are basically six antennal segments, but in the 4th instar the 5th segment, and in the 5th instar the 5th and 6th segments (counting from the base), are usually sub-divided each into two segments. The sub-division of these antennal segments may occur in one but not the other antenna of a single specimen.

Wing pad development may also be used to distinguish most of the stages, as the following key indicates.

- | | |
|---|------------------|
| (1) No wing pads present | I and II instars |
| Wing pads present | 2 |
| (2) Wing pads on mesothorax only | III instar |
| Wing pads on both meso- and meta-thorax | 3 |
| (3) Wing pads scarcely longer than wide at the base | IV instar |
| Wing pads distinctly longer than wide at the base | V instar |

The five instars described here probably correspond to those recognized by Kershaw⁴ although he did not give any detailed descriptions. Neither Williams² nor Ulrich¹ distinguished between the true first and second stage nymphs. Their descriptions of "second", "third" and "fourth" correspond to the true third, fourth and fifth instars. Gough³ arrived at five instars by splitting the true fifth instar into two separate stages. He was probably misled by a change of appearance in the fifth instar a few days before moulting, due to the development of the adult cuticle and pigments within the nymphal exoskeleton.
